About This Guide

Table of Contents

This guide describes the Performance Co-Pilot (PCP) performance analysis toolkit. PCP provides a systems-level suite of tools that cooperate to deliver distributed performance monitoring and performance management services spanning hardware platforms, operating systems, service layers, database internals, user applications and distributed architectures.

PCP is a cross-platform, open source software package - customizations, extensions, source code inspection, and tinkering in general is actively encouraged.

“About This Guide” includes short descriptions of the chapters in this book, directs you to additional sources of information, and explains typographical conventions.

What This Guide Contains

This guide contains the following chapters:

- Chapter 1, *Introduction to PCP*, provides an introduction, a brief overview of the software components, and conceptual foundations of the PCP software.
- Chapter 2, *Installing and Configuring Performance Co-Pilot*, describes the basic installation and configuration steps necessary to get PCP running on your systems.
- Chapter 3, *Common Conventions and Arguments*, describes the user interface components that are common to most of the text-based utilities that make up the monitor portion of PCP.
- Chapter 4, *Monitoring System Performance*, describes the performance monitoring tools available in Performance Co-Pilot (PCP).
- Chapter 5, *Performance Metrics Inference Engine*, describes the Performance Metrics Inference Engine (**pmie**) tool that provides automated monitoring of, and reasoning about, system performance within the PCP framework.
- Chapter 6, *Archive Logging*, covers the PCP services and utilities that support archive logging for capturing accurate historical performance records.
- Chapter 7, *Performance Co-Pilot Deployment Strategies*, presents the various options for deploying PCP functionality across cooperating systems.
- Chapter 8, *Customizing and Extending PCP Services*, describes the procedures necessary to ensure that the PCP configuration is customized in ways that maximize the coverage and quality of performance monitoring and management services.

- Appendix A, *Acronyms*, provides a comprehensive list of the acronyms used in this guide and in the man pages for Performance Co-Pilot.

Audience for This Guide

This guide is written for the system administrator or performance analyst who is directly using and administering PCP applications.

Related Resources

The *Performance Co-Pilot Programmer's Guide*, a companion document to the *Performance Co-Pilot User's and Administrator's Guide*, is intended for developers who want to use the PCP framework and services for exporting additional collections of performance metrics, or for delivering new or customized applications to enhance performance management.

The *Performance Co-Pilot Tutorials and Case Studies* provides a series of real-world examples of using various PCP tools, and lessons learned from deploying the toolkit in production environments. It serves to provide reinforcement of the general concepts discussed in the other two books with additional case studies, and in some cases very detailed discussion of specifics of individual tools.

Additional resources include man pages and the project web site.

Man Pages

The operating system man pages provide concise reference information on the use of commands, subroutines, and system resources. There is usually a man page for each PCP command or subroutine. To see a list of all the PCP man pages, start from the following command:

```
man PCPIntro
```

Each man page usually has a "SEE ALSO" section, linking to other, related entries.

To see a particular man page, supply its name to the `man` command, for example:

```
man pcp
```

The man pages are arranged in different sections - user commands, programming interfaces, and so on. For a complete list of manual sections on a platform enter the command:

```
man man
```

When referring to man pages, this guide follows a standard convention: the section number in parentheses follows the item. For example, **pminfo(1)** refers to the man page in section 1 for the **pminfo** command.

Web Site

The following web site is accessible to everyone:

URL	Description
https://pcp.io	PCP is open source software released under the GNU General Public License (GPL) and GNU Lesser General Public License (LGPL)

Conventions

The following conventions are used throughout this document:

Convention	Meaning
`${PCP_VARIABLE}`	A brace-enclosed all-capital-letters syntax indicates a variable that has been sourced from the global `${PCP_DIR}/etc/pcp.conf` file. These special variables indicate parameters that affect all PCP commands, and are likely to be different between platforms.
`command`	This fixed-space font denotes literal items such as commands, files, routines, path names, signals, messages, and programming language structures.
`variable`	Italic typeface denotes variable entries and words or concepts being defined.
`user input`	This bold, fixed-space font denotes literal items that the user enters in interactive sessions. (Output is shown in nonbold, fixed-space font.)
[ ]	Brackets enclose optional portions of a command or directive line.
...	Ellipses indicate that a preceding element can be repeated.
ALL CAPS	All capital letters denote environment variables, operator names, directives, defined constants, and macros in C programs.
()	Parentheses that follow function names surround function arguments or are empty if the function has no arguments; parentheses that follow commands surround man page section numbers.

Reader Comments

If you have comments about the technical accuracy, content, or organization of this document, contact the PCP maintainers using either the email address or the web site listed earlier.

We value your comments and will respond to them promptly.

Chapter 1. Introduction to PCP

Table of Contents

This chapter provides an introduction to Performance Co-Pilot (PCP), an overview of its individual components, and conceptual information to help you use this software.

The following sections are included:

- the section called “Objectives” covers the intended purposes of PCP.
- the section called “Overview of Component Software”, describes PCP tools and agents.
- the section called “Conceptual Foundations”, discusses the design theories behind PCP.

Objectives

Performance Co-Pilot (PCP) provides a range of services that may be used to monitor and manage system performance. These services are distributed and scalable to accommodate the most complex system configurations and performance problems.

PCP Target Usage

PCP is targeted at the performance analyst, benchmarker, capacity planner, developer, database administrator, or system administrator with an interest in overall system performance and a need to quickly isolate and understand performance behavior, resource utilization, activity levels, and bottlenecks in complex systems. Platforms that can benefit from this level of performance analysis include large servers, server clusters, or multiserver sites delivering Database Management Systems (DBMS), compute, Web, file, or video services.

Empowering the PCP User

To deal efficiently with the dynamic behavior of complex systems, performance analysts need to filter out noise from the overwhelming stream of performance data, and focus on exceptional scenarios. Visualization of current and historical performance data, and automated reasoning about performance data, effectively provide this filtering.

From the PCP end user's perspective, PCP presents an integrated suite of tools, user interfaces, and services that support real-time and retrospective performance analysis, with a bias towards eliminating mundane information and focusing attention on the exceptional and extraordinary performance behaviors. When this is done, the user can concentrate on in-depth analysis or target management procedures for those critical system performance problems.

Unification of Performance Metric Domains

At the lowest level, performance metrics are collected and managed in autonomous performance domains such as the operating system kernel, a DBMS, a layered service, or an end-user application. These domains feature a multitude of access control policies, access methods, data semantics, and multiversion support. All this detail is irrelevant to the developer or user of a performance monitoring tool, and is hidden by the PCP infrastructure.

Performance Metrics Domain Agents (PMDAs) within PCP encapsulate the knowledge about, and export performance information from, autonomous performance domains.

Uniform Naming and Access to Performance Metrics

Usability and extensibility of performance management tools mandate a single scheme for naming performance metrics. The set of defined names constitutes a Performance Metrics Name Space (PMNS). Within PCP, the PMNS is adaptive so it can be extended, reshaped, and pruned to meet the needs of particular applications and users.

PCP provides a single interface to name and retrieve values for all performance metrics, independently of their source or location.

PCP Distributed Operation

From a purely pragmatic viewpoint, a single workstation must be able to monitor the concurrent performance of multiple remote hosts. At the same time, a single host may be subject to monitoring from multiple remote workstations.

These requirements suggest a classic client-server architecture, which is exactly what PCP uses to provide concurrent and multiconnected access to performance metrics, independent of their host location.

Dynamic Adaptation to Change

Complex systems are subject to continual changes as network connections fail and are reestablished; nodes are taken out of service and rebooted; hardware is added and removed; and software is upgraded, installed, or removed. Often these changes are asynchronous and remote (perhaps in another geographic region or domain of administrative control).

The distributed nature of the PCP (and the modular fashion in which performance metrics domains can be installed, upgraded, and configured on different hosts) enables PCP to adapt concurrently to changes in the monitored system(s). Variations in the available performance metrics as a consequence of configuration changes are handled automatically and become visible to all clients as soon as the reconfigured host is rebooted or the responsible agent is restarted.

PCP also detects loss of client-server connections, and most clients support subsequent automated reconnection.

Logging and Retrospective Analysis

A range of tools is provided to support flexible, adaptive logging of performance metrics for archive, playback, remote diagnosis, and capacity planning. PCP archive logs may be accumulated either at the host being monitored, at a monitoring workstation, or both.

A universal replay mechanism, modeled on media controls [http://en.wikipedia.org/wiki/Media_controls], supports play, step, rewind, fast forward and variable speed processing of archived performance data. Replay for multiple archives, from multiple hosts, is facilitated by an archive aggregation concept.

Most PCP applications are able to process archive logs and real-time performance data with equal facility. Unification of real-time access and access to the archive logs, in conjunction with the media controls, provides powerful mechanisms for building performance tools and to review both current and historical performance data.

Automated Operational Support

For operational and production environments, PCP provides a framework with scripts to customize in order to automate the execution of ongoing tasks such as these:

- Centralized archive logging for multiple remote hosts
- Archive log rotation, consolidation, and culling
- Web-based publishing of charts showing snapshots of performance activity levels in the recent past
- Flexible alarm monitoring: parameterized rules to address common critical performance scenarios and facilities to customize and refine this monitoring
- Retrospective performance audits covering the recent past; for example, daily or weekly checks for performance regressions or quality of service problems

PCP Extensibility

PCP permits the integration of new performance metrics into the PMNS, the collection infrastructure, and the logging framework. The guiding principle is, “if it is important for monitoring system performance, and you can measure it, you can easily integrate it into the PCP framework.”

For many PCP users, the most important performance metrics are not those already supported, but new performance metrics that characterize the essence of good or bad performance at their site, or within their particular application environment.

One example is an application that measures the round-trip time for a benign “probe” transaction against some mission-critical application.

For application developers, a library is provided to support easy-to-use insertion of trace and monitoring points within an application, and the automatic export of resultant performance data into the PCP framework. Other libraries and tools aid the development of customized and fully featured Performance Metrics Domain Agents (PMDAs).

Extensive source code examples are provided in the distribution, and by using the PCP toolkit and interfaces, these customized measures of performance or quality of service can be easily and seamlessly integrated into the PCP framework.

Metric Coverage

The core PCP modules support export of performance metrics that include kernel instrumentation, hardware instrumentation, process-level resource utilization, database and other system services instrumentation, and activity in the PCP collection infrastructure.

The supplied agents support thousands of distinct performance metrics, many of which can have multiple values, for example, per disk, per CPU, or per process.

Conceptual Foundations

The following sections provide a detailed overview of concepts that underpin Performance Co-Pilot (PCP).

Performance Metrics

Across all of the supported performance metric domains, there are a large number of performance metrics. Each metric has its own structure and semantics. PCP presents a uniform interface to these metrics, independent of the underlying metric data source.

The Performance Metrics Name Space (PMNS) provides a hierarchical classification of human-readable metric names, and a mapping from these external names to internal metric identifiers. See the section called “Performance Metrics Name Space”, for a description of the PMNS.

Performance Metric Instances

When performance metric values are returned to a requesting application, there may be more than one value instance for a particular metric; for example, independent counts for each CPU, process, disk, or local filesystem. Internal instance identifiers correspond one to one with external (human-readable) descriptions of the members of an instance domain.

Transient performance metrics (such as per-process information) cause repeated requests for the same metric to return different numbers of values, or changes in the particular instance identifiers returned. These changes are expected and fully supported by the PCP infrastructure; however, metric instantiation is guaranteed to be valid only at the time of collection.

Current Metric Context

When performance metrics are retrieved, they are delivered in the context of a particular source of metrics, a point in time, and a profile of desired instances. This means that the application making the request has already negotiated to establish the context in which the request should be executed.

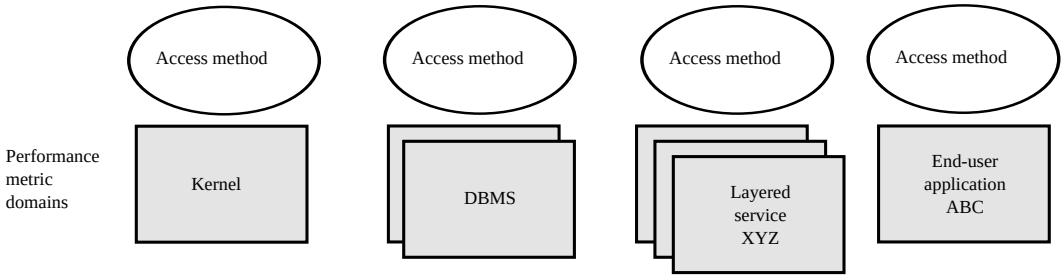
A metric source may be the current performance data from a particular host (a live or real-time source), or a set of archive logs of performance data collected by **pmlogger** at some distant host or at an earlier time (a retrospective or archive source).

By default, the collection time for a performance metric is the current time of day for real-time sources, or current point within an archive source. For archives, the collection time may be reset to an arbitrary time within the bounds of the set of archive logs.

Sources of Performance Metrics and Their Domains

Instrumentation for the purpose of performance monitoring typically consists of counts of activity or events, attribution of resource consumption, and service-time or response-time measures. This instrumentation may exist in one or more of the functional domains as shown in Figure 1.1, “Performance Metric Domains as Autonomous Collections of Data”.

Figure 1.1. Performance Metric Domains as Autonomous Collections of Data



Each domain has an associated access method:

- The operating system kernel, including sub-system data structures - per-process resource consumption, network statistics, disk activity, or memory management instrumentation.
- A layered software service such as activity logs for a World Wide Web server or an email delivery server.
- An application program such as measured response time for a production application running a periodic and benign probe transaction (as often required in service level agreements), or rate of computation and throughput in jobs per minute for a batch stream.
- External equipment such as network routers and bridges.

For each domain, the set of performance metrics may be viewed as an abstract data type, with an associated set of methods that may be used to perform the following tasks:

- Interrogate the metadata that describes the syntax and semantics of the performance metrics
- Control (enable or disable) the collection of some or all of the metrics
- Extract instantiations (current values) for some or all of the metrics

We refer to each functional domain as a performance metrics domain and assume that domains are functionally, architecturally, and administratively independent and autonomous. Obviously the set of performance metrics domains available on any host is variable, and changes with time as software and hardware are installed and removed.

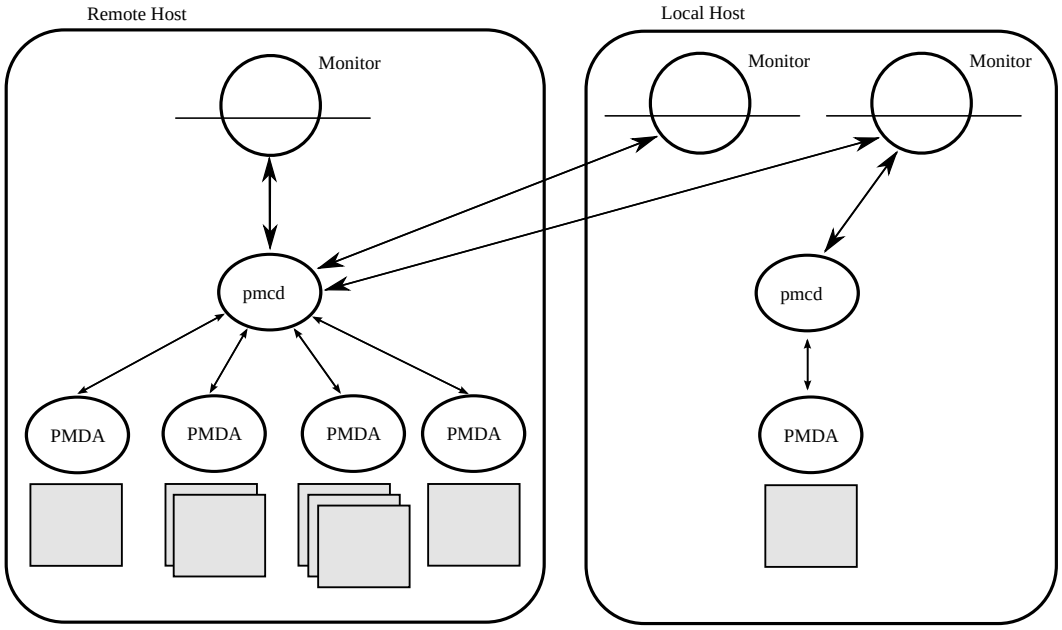
The number of performance metrics domains may be further enlarged in cluster-based or network-based configurations, where there is potentially an instance of each performance metrics domain on each node. Hence, the management of performance metrics domains must be both extensible at a particular host and distributed across a number of hosts.

Each performance metrics domain on a particular host must be assigned a unique Performance Metric Identifier (PMID). In practice, this means unique identifiers are assigned globally for each performance metrics domain type. For example, the same identifier would be used for the Apache Web Server performance metrics domain on all hosts.

Distributed Collection

The performance metrics collection architecture is distributed, in the sense that any performance tool may be executing remotely. However, a PMDA usually runs on the system for which it is collecting performance measurements. In most cases, connecting these tools together on the collector host is the responsibility of the PMCD process, as shown in Figure 1.2, “Process Structure for Distributed Operation”.

Figure 1.2. Process Structure for Distributed Operation



The host running the monitoring tools does not require any collection tools, including **pmcd**, because all requests for metrics are sent to the **pmcd** process on the collector host. These requests are then forwarded to the appropriate PMDAs, which respond with metric descriptions, help text, and most importantly, metric values.

The connections between monitor clients and `pmcd` processes are managed in `libpcp`, below the PMAPI level; see the **pmapi(3)** man page. Connections between PMDAs and **pmcd** are managed by the PMDA routines; see the **pmda(3)** man page. There can be multiple monitor clients and multiple PMDAs on the one host, but normally there would be only one `pmcd` process.

Performance Metrics Name Space

Internally, each unique performance metric is identified by a Performance Metric Identifier (PMID) drawn from a universal set of identifiers, including some that are reserved for site-specific, application-specific, and customer-specific use.

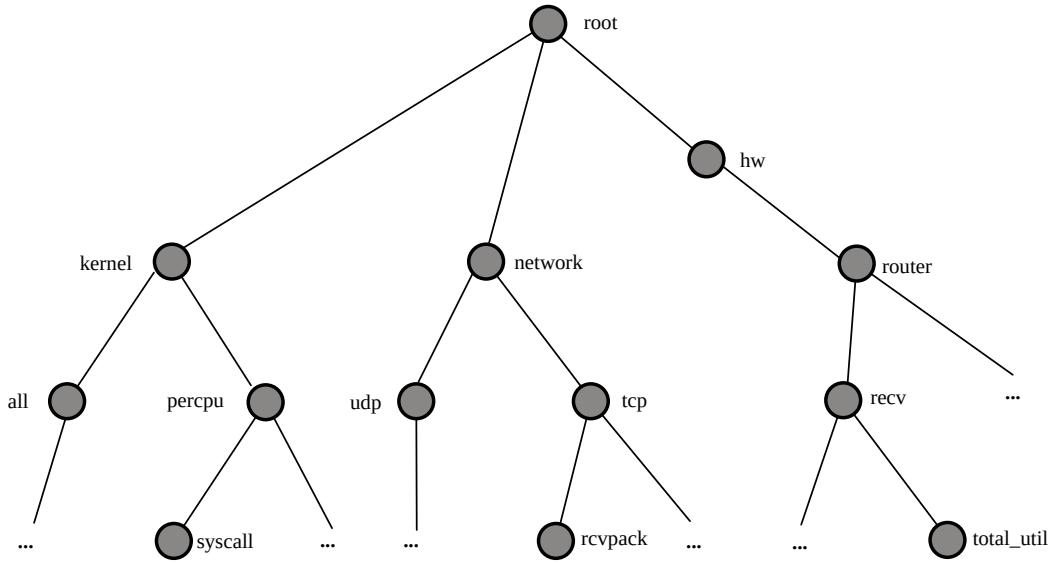
An external name space - the Performance Metrics Name Space (PMNS) - maps from a hierarchy (or tree) of human-readable names to PMIDs.

Performance Metrics Name Space Diagram

Each node in the PMNS tree is assigned a label that must begin with an alphabet character, and be followed by zero or more alphanumeric characters or the underscore (_) character. The root node of the tree has the special label of `root`.

A metric name is formed by traversing the tree from the root to a leaf node with each node label on the path separated by a period. The common prefix `root.` is omitted from all names. For example, Figure 1.3, “Small Performance Metrics Name Space (PMNS) ” shows the nodes in a small subsection of a PMNS.

Figure 1.3. Small Performance Metrics Name Space (PMNS)



In this subsection, the following are valid names for performance metrics:

```
kernel.percpu.syscall
network.tcp.rcvpack
hw.router.recv.total_util
```

Descriptions for Performance Metrics

Through the various performance metric domains, the PCP must support a wide range of formats and semantics for performance metrics. This *metadata* describing the performance metrics includes the following:

- The internal identifier, Performance Metric Identifier (PMID), for the metric
- The format and encoding for the values of the metric, for example, an unsigned 32-bit integer or a string or a 64-bit IEEE format floating point number

- The semantics of the metric, particularly the interpretation of the values as free-running counters or instantaneous values
- The dimensionality of the values, in the dimensions of events, space, and time
- The scale of values; for example, bytes, kilobytes (KB), or megabytes (MB) for the space dimension
- An indication if the metric may have one or many associated values
- Short (and extended) help text describing the metric

For each metric, this metadata is defined within the associated PMDA, and PCP arranges for the information to be exported to performance tools that use the metadata when interpreting the values for each metric.

Values for Performance Metrics

The following sections describe two types of performance metrics, single-valued and set-valued.

Single-Valued Performance Metrics

Some performance metrics have a singular value within their performance metric domains. For example, available memory (or the total number of context switches) has only one value per performance metric domain, that is, one value per host. The metadata describing the metric makes this fact known to applications that process values for these metrics.

Set-Valued Performance Metrics

Some performance metrics have a set of values or instances in each implementing performance metric domain. For example, one value for each disk, one value for each process, one value for each CPU, or one value for each activation of a given application.

When a metric has multiple instances, the PCP framework does not pollute the Name Space with additional metric names; rather, a single metric may have an associated set of values. These multiple values are associated with the members of an *instance domain*, such that each instance has a unique instance identifier within the associated instance domain. For example, the “per CPU” instance domain may use the instance identifiers 0, 1, 2, 3, and so on to identify the configured processors in the system.

Internally, instance identifiers are encoded as binary values, but each performance metric domain also supports corresponding strings as external names for the instance identifiers, and these names are used at the user interface to the PCP utilities.

For example, the performance metric `disk.dev.total` counts I/O operations for each disk spindle, and the associated instance domain contains one member for each disk spindle. On a system with five specific disks, one value would be associated with each of the external and internal instance identifier pairs shown in Table 1.1, “Sample Instance Identifiers for Disk Statistics ”.

Table 1.1. Sample Instance Identifiers for Disk Statistics

External Instance Identifier	Internal Instance Identifier
disk0	131329
disk1	131330
disk2	131331
disk3	131841
disk4	131842

Multiple performance metrics may be associated with a single instance domain.

Each performance metric domain may dynamically establish the instances within an instance domain. For example, there may be one instance for the metric `kernel.percpu.idle` on a workstation, but multiple instances on a multiprocessor server. Even more dynamic is `filesys.free`, where the values report the amount of free space per file system, and the number of values tracks the mounting and unmounting of local filesystems.

PCP arranges for information describing instance domains to be exported from the performance metric domains to the applications that require this information. Applications may also choose to retrieve values for all instances of a performance metric, or some arbitrary subset of the available instances.

Collector and Monitor Roles

Hosts supporting PCP services are broadly classified into two categories:

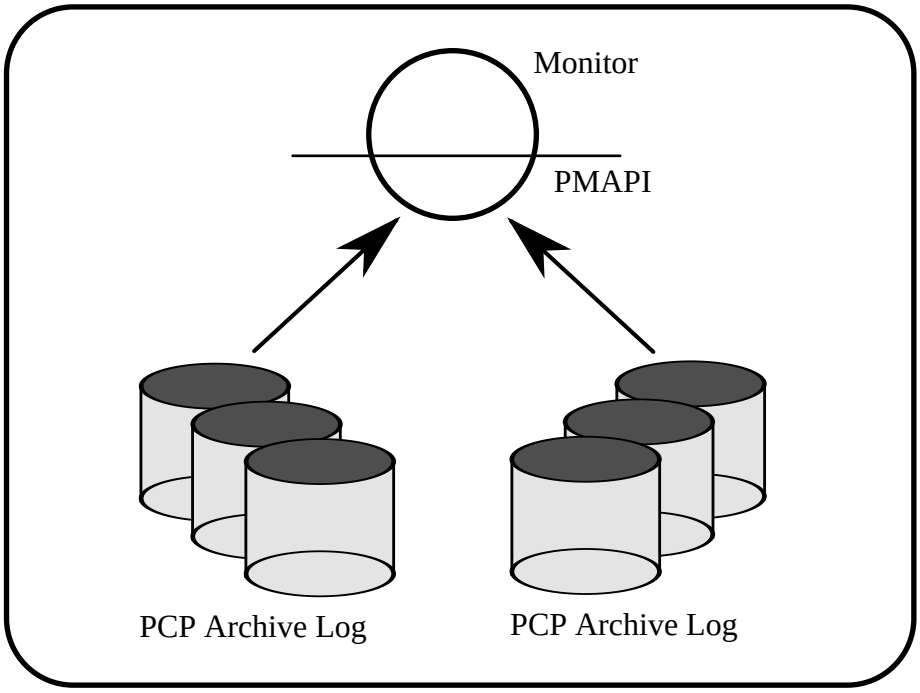
Collector	Hosts that have `pmcd` and one or more performance metric domain agents (PMDAs) running to collect and export performance metrics
Monitor	Hosts that import performance metrics from one or more collector hosts to be consumed by tools to monitor, manage, or record the performance of the collector hosts

Each PCP enabled host can operate as a collector, a monitor, or both.

Retrospective Sources of Performance Metrics

The PMAPI also supports delivery of performance metrics from a historical source in the form of a PCP archive log. Archive logs are created using the `pmlogger` utility, and are replayed in an architecture as shown in Figure 1.4, “Architecture for Retrospective Analysis”.

Figure 1.4. Architecture for Retrospective Analysis



The PMAPI has been designed to minimize the differences required for an application to process performance data from an archive or from a real-time source. As a result, most PCP tools support live and retrospective monitoring with equal facility.

Product Extensibility

Much of the PCP software's potential for attacking difficult performance problems in production environments comes from the design philosophy that considers extensibility to be critically important.

The performance analyst can take advantage of the PCP infrastructure to deploy value-added performance monitoring tools and services. Here are some examples:

- Easy extension of the PCP collector to accommodate new performance metrics and new sources of performance metrics, in particular using the interfaces of a special-purpose library to develop new PMDAs (see the **pmda(3)** man page)
- Use of libraries (`libpcp_pmda` and `libpcp_mmv`) to aid in the development of new capabilities to export performance metrics from local applications
- Operation on any performance metric using generalized toolkits
- Distribution of PCP components such as collectors across the network, placing the service where it can do the most good
- Dynamic adjustment to changes in system configuration
- Flexible customization built into the design of all PCP tools
- Creation of new monitor applications, using the routines described in the **pmapi(3)** man page

Overview of Component Software

Performance Co-Pilot (PCP) is composed of both text-based and graphical tools. Each tool is fully documented by a man page. These man pages are named after the tools or commands they describe, and are accessible through the **man** command. For example, to see the **pminfo(1)** man page for the **pminfo** command, enter this command:

```
man pminfo
```

A representative list of PCP tools and commands, grouped by functionality, is provided in the following four sections.

Performance Monitoring and Visualization

The following tools provide the principal services for the PCP end-user with an interest in monitoring, visualizing, or processing performance information collected either in real time or from PCP archive logs:

pcp-atop — Full-screen monitor of the load on a system from a kernel, hardware and processes point of view. It is modeled on the Linux **atop(1)** tool (home page [http://www.atoptool.nl/]) and provides a showcase for the variety of data available using PCP services and the Python scripting interfaces.

pmchart — Strip chart tool for arbitrary performance metrics. Interactive graphical utility that can display multiple charts simultaneously, from multiple hosts or set of archives, aligned on a unified time axis (X-axis), or on multiple tabs.

pcp-collectl Statistics collection tool with good coverage of a number of Linux kernel subsystems, with the everything-in-one-tool approach pioneered by **sar(1)**. It is modeled on the Linux **collectl(1)** utility (home page [http://collectl.sourceforge.net/]) and provides another example of use of the Python scripting interfaces to build more complex functionality with relative ease, with PCP as a foundation.

pmrep Outputs the values of arbitrary performance metrics collected live or from a single PCP archive, in textual format.

pmevent Reports on event metrics, decoding the timestamp and event parameters for text-based reporting.

pmie Evaluates predicate-action rules over performance metrics for alarms, automated system management tasks, dynamic configuration tuning, and so on. It is an inference engine.

pmieconf Creates parameterized rules to be used with the PCP inference engine (**pmie**). It can be run either interactively or from scripts for automating the setup of inference (the PCP start scripts do this, for example, to generate a default configuration).

pminfo Displays information about arbitrary performance metrics available from PCP, including help text with `-T`.

pmlogsummary Calculates and reports various statistical summaries of the performance metric values from a set of PCP archives.

pmprobe Probes for performance metric availability, values, and instances.

pmstat Provides a text-based display of metrics that summarize the performance of one or more systems at a high level.

pmval Provides a text-based display of the values for arbitrary instances of a selected performance metric, suitable for ASCII logs or inquiry over a slow link.

Collecting, Transporting, and Archiving Performance Information

PCP provides the following tools to support real-time data collection, network transport, and archive log creation services for performance data:

mkaf Aggregates an arbitrary collection of PCP archive logs into a *folio* to be used with **pmafm**.

pmafm Interrogates, manages, and replays an archive folio as created by **mkaf**, or the periodic archive log management scripts, or the record mode of other PCP tools.

pmcd Is the Performance Metrics Collection Daemon (PMCD). This daemon must run on each system being monitored, to collect and export the performance information necessary to monitor the system.

pmcd_wait	Waits for **pmcd** to be ready to accept client connections.
pmdaapache	Exports performance metrics from the Apache Web Server. It is a Performance Metrics Domain Agent (PMDA).
pmdacisco	Extracts performance metrics from one or more Cisco routers.
pmdaelasticseach	Extracts performance metrics from an elasticsearch cluster.
pmdagfs2	Exports performance metrics from the GFS2 clustered filesystem.
pmdagluster	Extracts performance metrics from the Gluster filesystem.
pmdainfiniband	Exports performance metrics from the Infiniband kernel driver.
pmdakvm	Extracts performance metrics from the Linux Kernel Virtual Machine (KVM) infrastructure.
pmdalustrecomm	Exports performance metrics from the Lustre clustered filesystem.
pmdamailq	Exports performance metrics describing the current state of items in the `sendmail` queue.
pmdamemcache	Extracts performance metrics from memcached, a distributed memory caching daemon commonly used to improve web serving performance.
pmdammv	Exports metrics from instrumented applications linked with the `pcp_mmv` shared library or the Parfait [http://code.google.com/p/parfait/] framework for Java instrumentation. These metrics are custom developed per application, and in the case of Parfait, automatically include numerous JVM, Tomcat and other server or container statistics.
pmdamysql	Extracts performance metrics from the MySQL relational database.
pmdanamed	Exports performance metrics from the Internet domain name server, named.
pmdanginx	Extracts performance metrics from the nginx HTTP and reverse proxy server.
pmdapostfix	Export performance metrics from the Postfix mail transfer agent.
pmdapostgres	Extracts performance metrics from the PostgreSQL relational database.
pmdaproc	Exports performance metrics for running processes.
pmdarsyslog	Extracts performance metrics from the Reliable System Log daemon.
pmdasamba	Extracts performance metrics from Samba, a Windows SMB/CIFS server.
pmdasendmail	Exports mail activity statistics from **sendmail**.

pmdashping	Exports performance metrics for the availability and quality of service (response-time) for arbitrary shell commands.
pmdasnmp	Extracts SNMP performance metrics from local or remote SNMP-enabled devices.
pmdasummary	Derives performance metrics values from values made available by other PMDAs. It is a PMDA itself.
pmdasystemd	Extracts performance metrics from the systemd and journald services.
pmdatrace	Exports transaction performance metrics from application processes that use the `pcp_trace` library.
pmdavmware	Extracts performance metrics from a VMWare virtualization host.
pmdaweblog	Scans Web-server logs to extract metrics characterizing.
pmdaxfs	Extracts performance metrics from the Linux kernel XFS filesystem implementation.
pmdumplog	Displays selected state information, control data, and metric values from a set of PCP archive logs created by **pmlogger**.
pmlc	Exercises control over an instance of the PCP archive logger **pmlogger**, to modify the profile of which metrics are logged and/or how frequently their values are logged.
pmlogcheck	Performs integrity check for individual PCP archives.
pmlogconf	Creates or modifies **pmlogger** configuration files for many common logging scenarios, optionally probing for available metrics and enabled functionality. It can be run either interactively or from scripts for automating the setup of data logging (the PCP start scripts do this, for example, to generate a default configuration).
pmlogextract	Reads one or more PCP archive logs and creates a temporally merged and reduced PCP archive log as output.
pmlogger	Creates PCP archive logs of performance metrics over time. Many tools accept these PCP archive logs as alternative sources of metrics for retrospective analysis.
pmproxy	Provides REST APIs, archive discovery, and both PCP and Redis protocol proxying when executing PCP or Redis client tools through a network firewall system.
pmtrace	Provides a simple command line interface to the trace PMDA and its associated `pcp_trace` library.

Operational and Infrastructure Support

PCP provides the following tools to support the PCP infrastructure and assist operational procedures for PCP deployment in a production environment:

pcp Summarizes that state of a PCP installation.

pmdbg Describes the available facilities and associated control flags. PCP tools include internal diagnostic and debugging facilities that may be activated by run-time flags.

pmerr Translates PCP error codes into human-readable error messages.

pmhostname Reports hostname as returned by **gethostbyname**. Used in assorted PCP management scripts.

pmie_check Administration of the Performance Co-Pilot inference engine (**pmie**).

pmlock Attempts to acquire an exclusive lock by creating a file with a mode of 0.

pmlogger_* Allows you to create a customized regime of administration and management for PCP archive log files. The `pmlogger_check`, `pmlogger_daily`, and `pmlogger_merge` scripts are intended for periodic execution via the **cron** command.

pmnewlog Performs archive log rotation by stopping and restarting an instance of **pmlogger**.

pmnsadd Adds a subtree of new names into a PMNS, as used by the components of PCP.

pmnsdel Removes a subtree of names from a PMNS, as used by the components of the PCP.

pmnsmerge Merges multiple PMNS files together, as used by the components of PCP.

pmstore Reinitializes counters or assigns new values to metrics that act as control variables. The command changes the current values for the specified instances of a single performance metric.

Application and Agent Development

The following PCP tools aid the development of new programs to consume performance data, and new agents to export performance data within the PCP framework:

chkhelp Checks the consistency of performance metrics help database files.

dbpmda Allows PMDA behavior to be exercised and tested. It is an interactive debugger for PMDAs.

newhelp Generates the database files for one or more source files of PCP help text.

pmapi Defines a procedural interface for developing PCP client applications. It is the Performance Metrics Application Programming Interface (PMAPI).

pmclient Is a simple client that uses the PMAPI to report some high-level system performance metrics.

pmda Is a library used by many shipped PMDAs to communicate with a **pmcd** process. It can expedite the development of new and custom PMDAs.

pmgenmap Generates C declarations and **cpp(1)** macros to aid the development of customized programs that use the facilities of PCP. It is a PMDA development tool.

Chapter 2. Installing and Configuring Performance Co-Pilot

Table of Contents

The sections in this chapter describe the basic installation and configuration steps necessary to run Performance Co-Pilot (PCP) on your systems. The following major sections are included:

- the section called “Product Structure” describes the main packages of PCP software and how they must be installed on each system.
- the section called “Performance Metrics Collection Daemon (PMCD)”, describes the fundamentals of maintaining the performance data collector.
- the section called “Managing Optional PMDAs”, describes the basics of installing a new Performance Metrics Domain Agent (PMDA) to collect metric data and pass it to the PMCD.
- the section called “Troubleshooting”, offers advice on problems involving the PMCD.

Product Structure

In a typical deployment, Performance Co-Pilot (PCP) would be installed in a collector configuration on one or more hosts, from which the performance information could then be collected, and in a monitor configuration on one or more workstations, from which the performance of the server systems could then be monitored.

On some platforms Performance Co-Pilot is presented as multiple packages; typically separating the server components from graphical user interfaces and documentation.

pcp-X.Y.Z-*rev*	package for core PCP
pcp-gui-X.Y.Z-*rev*	package for graphical PCP client tools
pcp-doc-X.Y.Z-*rev*	package for online PCP documentation

Performance Metrics Collection Daemon (PMCD)

On each Performance Co-Pilot (PCP) collection system, you must be certain that the **pmcd** daemon is running. This daemon coordinates the gathering and exporting of performance statistics in response to requests from the PCP monitoring tools.

Starting and Stopping the PMCD

To start the daemon, enter the following commands as `root` on each PCP collection system:

```
chkconfig pmcd on
${PCP_RC_DIR}/pmcd start
```

These commands instruct the system to start the daemon immediately, and again whenever the system is booted. It is not necessary to start the daemon on the monitoring system unless you wish to collect performance information from it as well.

To stop **pmcd** immediately on a PCP collection system, enter the following command:

```
${PCP_RC_DIR}/pmcd stop
```

Restarting an Unresponsive PMCD

Sometimes, if a daemon is not responding on a PCP collection system, the problem can be resolved by stopping and then immediately restarting a fresh instance of the daemon. If you need to stop and then immediately restart PMCD on a PCP collection system, use the `start` argument provided with the script in `${PCP_RC_DIR}`. The command syntax is, as follows:

```
${PCP_RC_DIR}/pmcd start
```

On startup, **pmcd** looks for a configuration file at `${PCP_PMCDCONF_PATH}`. This file specifies which agents cover which performance metrics domains and how PMCD should make contact with the agents. A comprehensive description of the configuration file syntax and semantics can be found in the **pmcd(1)** man page.

If the configuration is changed, **pmcd** reconfigures itself when it receives the `SIGHUP` signal. Use the following command to send the `SIGHUP` signal to the daemon:

```
${PCP_BINADM_DIR}/pmsignal -a -s HUP pmcd
```

This is also useful when one of the PMDAs managed by **pmcd** has failed or has been terminated by **pmcd**. Upon receipt of the `SIGHUP` signal, **pmcd** restarts any PMDA that is configured but inactive. The exception to this rule is the case of a PMDA which must run with superuser privileges (where possible, this is avoided) - for these PMDAs, a full **pmcd** restart must be performed, using the process described earlier (not SIGHUP).

PMCD Diagnostics and Error Messages

If there is a problem with **pmcd**, the first place to investigate should be the `pmcd.log` file. By default, this file is in the `${PCP_LOG_DIR}/pmcd` directory.

PMCD Options and Configuration Files

There are two files that control PMCD operation. These are the `${PCP_PMCDCONF_PATH}` and `${PCP_PMCDOPTIONS_PATH}` files. The `pmcd.options` file contains the command line options used with PMCD; it is read when the daemon is invoked by `${PCP_RC_DIR}/pmcd`. The `pmcd.conf` file contains configuration information regarding domain agents and the metrics that they monitor. These configuration files are described in the following sections.

The `pmcd.options` File

Command line options for the PMCD are stored in the `${PCP_PMCDOPTIONS_PATH}` file. The PMCD can be invoked directly from a shell prompt, or it can be invoked by `${PCP_RC_DIR}/pmcd` as part of the boot process. It is usual and normal to invoke it using `${PCP_RC_DIR}/pmcd`, reserving shell invocation for debugging purposes.

The PMCD accepts certain command line options to control its execution, and these options are placed in the `pmcd.options` file when `${PCP_RC_DIR}/pmcd` is being used to start the daemon. The following options (amongst others) are available:

`-i` *address*
: For hosts with more than one network interface, this option specifies the interface on which this instance of the PMCD accepts connections. Multiple `-i` options may be specified. The default in the absence of any `-i` option is for PMCD to accept connections on all interfaces.

-l *file*
: Specifies a log file. If no `-l` option is specified, the log file name is `pmcd.log` and it is created in the directory `${PCP_LOG_DIR}/pmcd/`.

-s *file*
: Specifies the path to a local unix domain socket (for platforms supporting this socket family only). The default value is `${PCP_RUN_DIR}/pmcd.socket`.

-t *seconds*
: Specifies the amount of time, in seconds, before PMCD times out on protocol data unit (PDU) exchanges with PMDAs. If no time out is specified, the default is five seconds. Setting time out to zero disables time outs (not recommended, PMDAs should always respond quickly).

  The time out may be dynamically modified by storing the number of seconds into the metric `pmcd.control.timeout` using **pmstore**.

`-T` *mask*
: Specifies whether connection and PDU tracing are turned on for debugging purposes.

See the **pmcd(1)** man page for complete information on these options.

The default `pmcd.options` file shipped with PCP is similar to the following:

```
# command-line options to pmcd, uncomment/edit lines as required

# longer timeout delay for slow agents
# -t 10

# suppress timeouts
# -t 0
```

```
# make log go someplace else
# -l /some/place/else

# debugging knobs, see pmdbg(1)
# -D N
# -f

# Restricting (further) incoming PDU size to prevent DOS attacks
# -L 16384

# enable event tracing bit fields
#   1   trace connections
#   2   trace PDUs
# 256   unbuffered tracing
# -T 3

# setting of environment variables for pmcd and
# the PCP rc scripts. See pmcd(1) and PMAPI(3).
# PMCD_WAIT_TIMEOUT=120
```

The most commonly used options have been placed in this file for your convenience. To uncomment and use an option, simply remove the pound sign (#) at the beginning of the line with the option you wish to use. Restart **pmcd** for the change to take effect; that is, as superuser, enter the command:

```
${PCP_RC_DIR}/pmcd start
```

The `pmcd.conf` File

When the PMCD is invoked, it reads its configuration file, which is `${PCP_PMCDCONF_PATH}`. This file contains entries that specify the PMDAs used by this instance of the PMCD and which metrics are covered by these PMDAs. Also, you may specify access control rules in this file for the various hosts, users and groups on your network. This file is described completely in the **pmcd(1)** man page.

With standard PCP operation (even if you have not created and added your own PMDAs), you might need to edit this file in order to add any additional access control you wish to impose. If you do not add access control rules, all access for all operations is granted to the local host, and read-only access is granted to remote hosts. The `pmcd.conf` file is automatically generated during the software build process and on Linux, for example, is similar to the following:

```
 Performance Metrics Domain Specifications
#
# This file is automatically generated during the build
# Name  Id      IPC     IPC Params      File/Cmd
root 1 pipe binary  /var/lib/pcp/pmdas/root/pmdaroot
pmcd    2       dso     pmcd_init       ${PCP_PMDAS_DIR}/pmcd/pmda_pmcd.so
proc    3       pipe    binary          ${PCP_PMDAS_DIR}/proc/pmdaproc -d 3
xfs     11      pipe    binary          ${PCP_PMDAS_DIR}/xfs/pmdaxfs -d 11
linux   60      dso     linux_init      ${PCP_PMDAS_DIR}/linux/pmda_linux.so
mmv 70 dso mmv_init /var/lib/pcp/pmdas/mmv/pmda_mmv.so

[access]
disallow ".*" : store;
disallow ":*" : store;
allow "local:*" : all;
```

Note

Even though PMCD does not run with `root` privileges, you must be very careful not to configure PMDAs in this file if you are not sure of their action. This is because all PMDAs are initially started as `root` (allowing them to assume alternate identities, such as `postgres` for example), after which **pmcd** drops its privileges. Pay close attention that permissions on this file are not inadvertently downgraded to allow public write access.

Each entry in this configuration file contains rules that specify how to connect the PMCD to a particular PMDA and which metrics the PMDA monitors. A PMDA may be attached as a Dynamic Shared Object (DSO) or by using a socket or a pair of pipes. The distinction between these attachment methods is described below.

An entry in the `pmcd.conf` file looks like this:

label_name domain_number type path

The *label_name* field specifies a name for the PMDA. The *domain_number* is an integer value that specifies a domain of metrics for the PMDA. The *type* field indicates the type of entry (DSO, socket, or pipe). The *path* field is for additional information, and varies according to the type of entry.

The following rules are common to DSO, socket, and pipe syntax:

label_name — An alphanumeric string identifying the agent.

domain_number — An unsigned integer specifying the agent's domain.

DSO entries follow this syntax:

label_name domain_number `dso` *entry-point path*

The following rules apply to the DSO syntax:

`dso` — The entry type.

entry-point — The name of an initialization function called when the DSO is loaded.

path — Designates the location of the DSO. An absolute path must be used. On most platforms this will be a `so` suffixed file, on Windows it is a `dll`, and on Mac OS X it is a `dylib` file.

Socket entries in the `pmcd.conf` file follow this syntax:

label_name domain_number `socket` *addr_family address command* [*args*]

The following rules apply to the socket syntax:

`socket` — The entry type.

addr_family — Specifies if the socket is `AF_INET`, `AF_IPV6` or `AF_UNIX`. If the socket is `INET`, the word `inet` appears in this place. If the socket is `IPV6`, the word `ipv6` appears in this place. If the socket is `UNIX`, the word `unix` appears in this place.

address — Specifies the address of the socket. For INET or IPv6 sockets, this is a port number or port name. For UNIX sockets, this is the name of the PMDA's socket on the local host.

command Specifies a command to start the PMDA when the PMCD is invoked and reads the configuration file.

args Optional arguments for *command*.

Pipe entries in the `pmcd.conf` file follow this syntax:

label_name domain_number pipe *protocol command* [*args*]

The following rules apply to the pipe syntax:

`pipe` The entry type.

protocol Specifies whether a text-based or a binary PCP protocol should be used over the pipes. Historically, this parameter was able to be "text" or "binary." The text-based protocol has long since been deprecated and removed, however, so nowadays "binary" is the only valid value here.

command Specifies a command to start the PMDA when the PMCD is invoked and reads the configuration file.

args Optional arguments for *command*.

Controlling Access to PMCD with `pmcd.conf`

You can place this option extension in the `pmcd.conf` file to control access to performance metric data based on hosts, users and groups. To add an access control section, begin by placing the following line at the end of your `pmcd.conf` file:

```
[access]
```

Below this line, you can add entries of the following forms:

```
allow hosts hostlist : operations ;   disallow hosts hostlist : operations ;
allow users userlist : operations ;   disallow users userlist : operations ;
allow groups grouplist : operations ;   disallow groups grouplist : operations ;
```

The keywords *users*, *groups* and *hosts* can be used in either plural or singular form.

The *userlist* and *grouplist* fields are comma-separated lists of authenticated users and groups from the local `/etc/passwd` and `/etc/groups` files, NIS (network information service) or LDAP (lightweight directory access protocol) service.

The *hostlist* is a comma-separated list of host identifiers; the following rules apply:

- Host names must be in the local system's `/etc/hosts` file or known to the local DNS (domain name service).
- IP and IPv6 addresses may be given in the usual numeric notations.
- A wildcarded IP or IPv6 address may be used to specify groups of hosts, with the single wildcard character * as the last-given component of the address. The wildcard .* refers to all IP (IPv4) addresses. The wildcard :* refers to all IPv6 addresses. If an IPv6 wildcard contains a :: component, then the final * refers to the final 16 bits of the address only, otherwise it refers to the remaining unspecified bits of the address.

The wildcard ``*'' refers to all users, groups or host addresses. Names of users, groups or hosts may not be wildcarded.

For example, the following *hostlist* entries are all valid:

```
babylon
babylon.acme.com
123.101.27.44
localhost
155.116.24.*
192.*
.*
fe80::223:14ff:feaf:b62c
fe80::223:14ff:feaf:*
fe80:*
:*
*
```

The *operations* field can be any of the following:

- A comma-separated list of the operation types described below.
- The word *all* to allow or disallow all operations as specified in the first field.
- The words *all except* and a list of operations. This entry allows or disallows all operations as specified in the first field except those listed.
- The phrase *maximum* N *connections* to set an upper bound (N) on the number of connections an individual host, user or group of users may make. This can only be added to the *operations* list of an allow statement.

The operations that can be allowed or disallowed are as follows:

`fetch` Allows retrieval of information from the PMCD. This may be information about a metric (such as a description, instance domain, or help text) or an actual value for a metric.

`store` Allows the PMCD to store metric values in PMDAs that permit store operations. Be cautious in allowing this operation, because it may be a security opening in large networks, although the PMDAs shipped with the PCP package typically reject store operations, except for selected performance metrics where the effect is benign.

For example, here is a sample access control portion of a `${PCP_PMCDCONF_PATH}` file:

```
allow hosts babylon, moomba : all ;
disallow user sam : all ;
allow group dev : fetch ;
allow hosts 192.127.4.* : fetch ;
disallow host gate-inet : store ;
```

Complete information on access control syntax rules in the `pmcd.conf` file can be found in the **pmcd(1)** man page.

Managing Optional PMDAs

Some Performance Metrics Domain Agents (PMDAs) shipped with Performance Co-Pilot (PCP) are designed to be installed and activated on every collector host, for example, `linux`, `windows`, `darwin`, `pmcd`, and `process` PMDAs.

Other PMDAs are designed for optional activation and require some user action to make them operational. In some cases these PMDAs expect local site customization to reflect the operational environment, the

system configuration, or the production workload. This customization is typically supported by interactive installation scripts for each PMDA.

Each PMDA has its own directory located below `${PCP_PMDAS_DIR}`. Each directory contains a `Remove` script to unconfigure the PMDA, remove the associated metrics from the PMNS, and restart the **pmcd** daemon; and an `Install` script to install the PMDA, update the PMNS, and restart the PMCD daemon.

As a shortcut mechanism to support automated PMDA installation, a file named `.NeedInstall` can be created in a PMDA directory below `${PCP_PMDAS_DIR}`. The next restart of PCP services will invoke that PMDAs installation automatically, with default options taken.

PMDA Installation on a PCP Collector Host

To install a PMDA you must perform a collector installation for each host on which the PMDA is required to export performance metrics. PCP provides a distributed metric namespace (PMNS) and metadata, so it is not necessary to install PMDAs (with their associated PMNS) on PCP monitor hosts.

You need to update the PMNS, configure the PMDA, and notify PMCD. The `Install` script for each PMDA automates these operations, as follows:

1. Log in as `root` (the superuser).

2. Change to the PMDA's directory as shown in the following example:

   `cd ${PCP_PMDAS_DIR}/cisco`

3. In the unlikely event that you wish to use a non-default Performance Metrics Domain (PMD) assignment, determine the current PMD assignment:

   `cat domain.h`

   Check that there is no conflict in the PMDs as defined in `${PCP_VAR_DIR}/pmns/stdpmid` and the other PMDAs currently in use (listed in `${PCP_PMCDCONF_PATH}`). Edit `domain.h` to assign the new domain number if there is a conflict (this is highly unlikely to occur in a regular PCP installation).

4. Enter the following command:

   `./Install`

   You may be prompted to enter some local parameters or configuration options. The script applies all required changes to the control files and to the PMNS, and then notifies PMCD. Example 2.1, “PMNS Installation Output ” is illustrative of the interactions:

Example 2.1. PMNS Installation Output

```
Cisco hostname or IP address? [return to quit] wanmelb

A user-level password may be required for Cisco “show int” command.
    If you are unsure, try the command
        $ telnet wanmelb
    and if the prompt “Password:” appears, a user-level password is
    required; otherwise answer the next question with an empty line.

User-level Cisco password? ********
```

```
Probing Cisco for list of interfaces ...

Enter interfaces to monitor, one per line in the format
tX where “t” is a type and one of “e” (Ethernet), or “f” (Fddi), or
“s” (Serial), or “a” (ATM), and “X” is an interface identifier
which is either an integer (e.g.  4000 Series routers) or two
integers separated by a slash (e.g. 7000 Series routers).

The currently unselected interfaces for the Cisco “wanmelb” are:
    e0 s0 s1
Enter “quit” to terminate the interface selection process.
Interface? [e0] s0

The currently unselected interfaces for the Cisco “wanmelb” are:
       e0 s1
Enter “quit” to terminate the interface selection process.
Interface? [e0] s1

The currently unselected interfaces for the Cisco “wanmelb” are:
    e0
Enter “quit” to terminate the interface selection process.
Interface? [e0] quit

Cisco hostname or IP address? [return to quit]
Updating the Performance Metrics Name Space (PMNS) ...
Installing pmchart view(s) ...
Terminate PMDA if already installed ...
Installing files ...
Updating the PMCD control file, and notifying PMCD ...
Check cisco metrics have appeared ... 5 metrics and 10 values
```

PMDA Removal on a PCP Collector Host

To remove a PMDA, you must perform a collector removal for each host on which the PMDA is currently installed.

The PMNS needs to be updated, the PMDA unconfigured, and PMCD notified. The `Remove` script for each PMDA automates these operations, as follows:

1. Log in as `root` (the superuser).
2. Change to the PMDA's directory as shown in the following example:

   ```
   cd ${PCP_PMDAS_DIR}/elasticsearch
   ```

3. Enter the following command:

   ```
   ./Remove
   ```

   The following output illustrates the result:

   ```
   Culling the Performance Metrics Name Space ...
   elasticsearch ... done
   Updating the PMCD control file, and notifying PMCD ...
   Removing files ...
   ```

```
Check elasticsearch metrics have gone away ... OK
```

Troubleshooting

The following sections offer troubleshooting advice on the Performance Metrics Name Space (PMNS), missing and incomplete values for performance metrics, kernel metrics and the PMCD.

Advice for troubleshooting the archive logging system is provided in Chapter 6, *Archive Logging*.

Performance Metrics Name Space

To display the active PMNS, use the `pminfo` command; see the **pminfo(1)** man page.

The PMNS at the collector host is updated whenever a PMDA is installed or removed, and may also be updated when new versions of PCP are installed. During these operations, the PMNS is typically updated by merging the (plaintext) namespace components from each installed PMDA. These separate PMNS components reside in the `${PCP_VAR_DIR}/pmns` directory and are merged into the `root` file there.

Missing and Incomplete Values for Performance Metrics

Missing or incomplete performance metric values are the result of their unavailability.

Metric Values Not Available

The following symptom has a known cause and resolution:

Symptom: Values for some or all of the instances of a performance metric are not available.

Cause: This can occur as a consequence of changes in the installation of modules (for example, a DBMS or an application package) that provide the performance instrumentation underpinning the PMDAs. Changes in the selection of modules that are installed or operational, along with changes in the version of these modules, may make metrics appear and disappear over time.

In simple terms, the PMNS contains a metric name, but when that metric is requested, no PMDA at the collector host supports the metric.

For archive logs, the collection of metrics to be logged is a subset of the metrics available, so utilities replaying from a PCP archive log may not have access to all of the metrics available from a live (PMCD) source.

Resolution: Make sure the underlying instrumentation is available and the module is active. Ensure that the PMDA is running on the host to be monitored. If necessary, create a new archive log with a wider range of metrics to be logged.

Kernel Metrics and the PMCD

The following issues involve the kernel metrics and the PMCD:

- Cannot connect to remote PMCD
- PMCD not reconfiguring after hang-up
- PMCD does not start

Cannot Connect to Remote PMCD

The following symptom has a known cause and resolution:

Symptom: A PCP client tool (such as `pmchart`, `pmie`, or `pmlogger`) complains that it is unable to connect to a remote PMCD (or establish a PMAPI context), but you are sure that PMCD is active on the remote host.

Cause: To avoid hanging applications for the duration of TCP/IP time outs, the PMAPI library implements its own time out when trying to establish a connection to a PMCD. If the connection to the host is over a slow network, then successful establishment of the connection may not be possible before the time out, and the attempt is abandoned.

Alternatively, there may be a firewall in-between the client tool and PMCD which is blocking the connection attempt.

Finally, PMCD may be running in a mode where it does not acept remote connections, or only listening on certain interface.

Resolution: Establish that the PMCD on *`far-away-host`* is really alive, by connecting to its control port (TCP port number 44321 by default):

```
telnet far-away-host 44321
```

This response indicates the PMCD is not running and needs restarting:

```
Unable to connect to remote host: Connection refused
```

To restart the PMCD on that host, enter the following command:

```
${PCP_RC_DIR}/pmcd start
```

This response indicates the PMCD is running:

```
Connected to far-away-host
```

Interrupt the `telnet` session, increase the PMAPI time out by setting the `PMCD_CONNECT_TIMEOUT` environment variable to some number of seconds (60 for instance), and try the PCP client tool again.

Verify that PMCD is not running in local-only mode, by looking for an enabled value (one) from:

```
pminfo -f pmcd.feature.local
```

This setting is controlled from the `PMCD_LOCAL` environment variable usually set via `${PCP_SYSCONFIG_DIR}/pmcd`.

If these techniques are ineffective, it is likely an intermediary firewall is blocking the client from accessing the PMCD port - resolving such issues is firewall-host platform-specific and cannot practically be covered here.

PMCD Not Reconfiguring after `SIGHUP`

The following symptom has a known cause and resolution:

Symptom: PMCD does not reconfigure itself after receiving the `SIGHUP` signal.

Cause: If there is a syntax error in `${PCP_PMCDCONF_PATH}`, PMCD does not use the contents of the file. This can lead to situations in which the configuration file and PMCD's internal state do not agree.

Resolution: Always monitor PMCD's log. For example, use the following command in another window when reconfiguring PMCD, to watch errors occur:

```
tail -f ${PCP_LOG_DIR}/pmcd/pmcd.log
```

PMCD Does Not Start

The following symptom has a known cause and resolution:

Symptom:

If the following messages appear in the PMCD log (`${PCP_LOG_DIR}/pmcd/pmcd.log`), consider the cause and resolution:

```
pcp[27020] Error: OpenRequestSocket(44321) bind: Address already
use
pcp[27020] Error: pmcd is already running
pcp[27020] Error: pmcd not started due to errors!
```

Cause: PMCD is already running or was terminated before it could clean up properly. The error occurs because the socket it advertises for client connections is already being used or has not been cleared by the kernel.

Resolution: Start PMCD as `root` (superuser) by typing:

```
${PCP_RC_DIR}/pmcd start
```

Any existing PMCD is shut down, and a new one is started in such a way that the symptomatic message should not appear.

If you are starting PMCD this way and the symptomatic message appears, a problem has occurred with the connection to one of the deceased PMCD's clients.

This could happen when the network connection to a remote client is lost and PMCD is subsequently terminated. The system may attempt to keep the socket open for a time to allow the remote client a chance to reestablish the connection and read any outstanding data.

The only solution in these circumstances is to wait until the socket times out and the kernel deletes it. This **netstat** command displays the status of the socket and any connections:

```
netstat -ant | grep 44321
```

If the socket is in the `FIN_WAIT` or `TIME_WAIT` state, then you must wait for it to be deleted. Once the command above produces no output, PMCD may be restarted. Less commonly, you may have another program running on your system that uses the same Internet port number (44321) that PMCD uses.

Refer to the **PCPIntro(1)** man page for a description of how to override the default PMCD port assignment using the `PMCD_PORT` environment variable.

Chapter 3. Common Conventions and Arguments

Table of Contents

This chapter deals with the user interface components that are common to most text-based utilities that make up the monitor portion of Performance Co-Pilot (PCP). These are the major sections in this chapter:

- the section called “Alternate Metrics Source Options”, details some basic standards used in the development of PCP tools.
- the section called “General PCP Tool Options”, details other options to use with PCP tools.
- the section called “Time Duration and Control”, describes the time control dialog and time-related command line options available for use with PCP tools.
- the section called “PCP Environment Variables”, describes the environment variables supported by PCP tools.
- the section called “Running PCP Tools through a Firewall”, describes how to execute PCP tools that must retrieve performance data from the Performance Metrics Collection Daemon (PMCD) on the other side of a TCP/IP security firewall.
- the section called “Transient Problems with Performance Metric Values ”, covers some uncommon scenarios that may compromise performance metric integrity over the short term.

Many of the utilities provided with PCP conform to a common set of naming and syntactic conventions for command line arguments and options. This section outlines these conventions and their meaning. The options may be generally assumed to be honored for all utilities supporting the corresponding functionality.

In all cases, the man pages for each utility fully describe the supported command arguments and options.

Command line options are also relevant when starting PCP applications from the desktop using the **Alt** double-click method. This technique launches the **pmrun** program to collect additional arguments to pass along when starting a PCP application.

Alternate Metrics Source Options

The default source of performance metrics is from PMCD on the local host. This default **pmcd** connection will be made using the Unix domain socket, if the platform supports that, else a localhost Inet socket connection is made. This section describes how to obtain metrics from sources other than this default.

Fetching Metrics from Another Host

The option `-h` *`host`* directs any PCP utility (such as `pmchart` or `pmie`) to make a connection with the PMCD instance running on *`host`*. Once established, this connection serves as the principal real-time source of performance metrics and metadata. The *`host`* specification may be more than a simple host name or address - it can also contain decorations specifying protocol type (secure or not), authentication information, and other connection attributes. Refer to the **PCPIntro(1)** man page for full details of these, and examples of use of these specifications can also be found in the *PCP Tutorials and Case Studies* companion document.

Fetching Metrics from an Archive Log

The option `-a`*`archive`* directs the utility to treat the set of PCP archive logs designated by *`archive`* as the principal source of performance metrics and metadata. *`archive`* is a comma-sparated list of names, each of which may be the base name of an archive or the name of a directory containing archives.

PCP archive logs are created with **pmlogger**. Most PCP utilities operate with equal facility for performance information coming from either a real-time feed via PMCD on some host, or for historical data from a set of PCP archive logs. For more information on archive logs and their use, see Chapter 6, *Archive Logging*.

The list of names (`archive`) used with the `-a` option implies the existence of the files created automatically by **pmlogger**, as listed in Table 3.1, “Physical Filenames for Components of a PCP Archive Log”.

Table 3.1. Physical Filenames for Components of a PCP Archive Log

Filename	Contents
`archive.` *`index`*	Temporal index for rapid access to archive contents
`archive.` *`meta`*	Metadata descriptions for performance metrics and instance domains appearing in the archive
`archive.N`	Volumes of performance metrics values, for `N` = 0,1,2,...

Most tools are able to concurrently process multiple PCP archive logs (for example, for retrospective analysis of performance across multiple hosts), and accept either multiple **-a** options or a comma separated list of archive names following the **-a** option.

Note

The **-h** and **-a** options are almost always mutually exclusive. Currently, **pmchart** is the exception to this rule but other tools may continue to blur this line in the future.

General PCP Tool Options

The following sections provide information relevant to most of the PCP tools. It is presented here in a single place for convenience.

Common Directories and File Locations

The following files and directories are used by the PCP tools as repositories for option and configuration files and for binaries:

`${PCP_DIR}/etc/pcp.env`	Script to set PCP run-time environment variables.
`${PCP_DIR}/etc/pcp.conf`	PCP configuration and environment file.
`${PCP_PMCDCONF_PATH}`	Configuration file for Performance Metrics Collection Daemon (PMCD). Sets environment variables, including `PATH`.
`${PCP_BINADM_DIR}/pmcd`	The PMCD binary.
`${PCP_PMCDOPTIONS_PATH}`	Command line options for PMCD.
`${PCP_RC_DIR}/pmcd`	The PMCD startup script.
`${PCP_BIN_DIR}/`*`pcptool`*	Directory containing PCP tools such as **pmstat** , **pminfo**, **pmlogger**, **pmlogsummary**, **pmchart**, **pmie**, and so on.
`${PCP_SHARE_DIR}`	Directory containing shareable PCP-specific files and repository directories such as **bin**, **demos**, **examples** and **lib**.
`${PCP_VAR_DIR}`	Directory containing non-shareable (that is, per-host) PCP specific files and repository directories.
`${PCP_BINADM_DIR}/`*`pcptool`*	PCP tools that are typically not executed directly by the end user such as **pmcd_wait**.
`${PCP_SHARE_DIR}/lib/`*`pcplib`*	Miscellaneous PCP libraries and executables.
`${PCP_PMDAS_DIR}`	Performance Metric Domain Agents (PMDAs), one directory per PMDA.
`${PCP_VAR_DIR}/config`	Configuration files for PCP tools, typically with one directory per tool.
`${PCP_DEMOS_DIR}`	Demonstration data files and example programs.
`${PCP_LOG_DIR}`	By default, diagnostic and trace log files generated by PMCD and PMDAs. Also, the PCP archive logs are managed in one directory per logged host below here.
`${PCP_VAR_DIR}/pmns`	Files and scripts for the Performance Metrics Name Space (PMNS).

Alternate Performance Metric Name Spaces

The Performance Metrics Name Space (PMNS) defines a mapping from a collection of human-readable names for performance metrics (convenient to the user) into corresponding internal identifiers (convenient for the underlying implementation).

The distributed PMNS used in PCP avoids most requirements for an alternate PMNS, because clients' PMNS operations are supported at the Performance Metrics Collection Daemon (PMCD) or by means of PMNS data in a PCP archive log. The distributed PMNS is the default, but alternates may be specified using the **-n** *namespace* argument to the PCP tools. When a PMNS is maintained on a host, it is likely to reside in the `${PCP_VAR_DIR}/pmns` directory.

Time Duration and Control

The periodic nature of sampling performance metrics and refreshing the displays of the PCP tools makes specification and control of the temporal domain a common operation. In the following sections, the services and conventions for specifying time positions and intervals are described.

Performance Monitor Reporting Frequency and Duration

Many of the performance monitoring utilities have periodic reporting patterns. The `-t` *interval* and `-s` *samples* options are used to control the sampling (reporting) interval, usually expressed as a real number of seconds (*interval*), and the number of *samples* to be reported, respectively. In the absence of the `-s` flag, the default behavior is for the performance monitoring utilities to run until they are explicitly stopped.

The *interval* argument may also be expressed in terms of minutes, hours, or days, as described in the **PCPIntro(1)** man page.

Time Window Options

The following options may be used with most PCP tools (typically when the source of the performance metrics is a PCP archive log) to tailor the beginning and end points of a display, the sample origin, and the sample time alignment to your convenience.

The `-S`, `-T`, `-O` and `-A` command line options are used by PCP applications to define a time window of interest.

`-S` *duration*

The start option may be used to request that the display start at the nominated time. By default, the first sample of performance data is retrieved immediately in real-time mode, or coincides with the first sample of data of the first archive in a set of PCP archive logs in archive mode. For archive mode, the `-S` option may be used to specify a later time for the start of sampling. By default, if *duration* is an integer, the units are assumed to be seconds.

To specify an offset from the beginning of a set of PCP archives (in archive mode) simply specify the offset as the *duration*. For example, the following entry retrieves the first sample of data at exactly 30 minutes from the beginning of a set of PCP archives.

```
-S 30min
```

To specify an offset from the end of a set of PCP archives, prefix the *duration* with a minus sign. In this case, the first sample time precedes the end of archived data by the given *duration*. For example, the following entry retrieves the first sample exactly one hour preceding the last sample in a set of PCP archives.

```
-S -1hour
```

To specify the calendar date and time (local time in the reporting timezone) for the first sample, use the `ctime(3)` syntax preceded by an "at" sign (@). For example, the following entry specifies the date and time to be used.

```
-S '@ Mon Mar 4 13:07:47 2017'
```

Note that this format corresponds to the output format of the **date** command for easy "cut and paste." However, be sure to enclose the string in quotes so it is preserved as a single argument for the PCP tool.

For more complete information on the date and time syntax, see the **PCPIntro(1)** man page.

`-T` *duration*

The terminate option may be used to request that the display stop at the time designated by *duration*. By default, the PCP tools keep sampling performance data indefinitely (in real-time mode) or until the end of a set of PCP archives (in archive mode). The `-T` option may be used to specify an earlier time to terminate sampling.

The interpretation for the *duration* argument in a `-T` option is the same as for the `-S` option, except for an unsigned time interval that is interpreted as being an offset from the start of the time window as defined by the default (now for real time, else start of archive set) or by a `-S` option. For example, these options define a time window that spans 45 minutes, after an initial offset (or delay) of 1 hour:

```
-S 1hour -T 45mins
```

`-O` *duration*

By default, samples are fetched from the start time (see the description of the `-S` option) to the terminate time (see the description of the `-T` option). The offset `-O` option allows the specification of a time between the start time and the terminate time where the tool should position its initial sample time. This option is useful when initial attention is focused at some point within a larger time window of interest, or when one PCP tool wishes to launch another PCP tool with a common current point of time within a shared time window.

The *duration* argument accepted by `-O` conforms to the same syntax and semantics as the *duration* argument for `-T`. For example, these options specify that the initial position should be the end of the time window:

```
-O -0
```

This is most useful with the **pmchart** command to display the tail-end of the history up to the end of the time window.

`-A` *`alignment`*
: By default, performance data samples do not necessarily happen at any natural unit of measured time. The `-A` switch may be used to force the initial sample to be on the specified *`alignment`*. For example, these three options specify alignment on seconds, half hours, and whole hours:

```
-A 1sec
-A 30min
-A 1hour
```

The `-A` option advances the time to achieve the desired alignment as soon as possible after the start of the time window, whether this is the default window, or one specified with some combination of `-A` and `-O` command line options.

Obviously the time window may be overspecified by using multiple options from the set `-t`, `-s`, `-S`, `-T`, `-A`, and `-O`. Similarly, the time window may shrink to nothing by injudicious choice of options.

In all cases, the parsing of these options applies heuristics guided by the principal of “least surprise”; the time window is always well-defined (with the end never earlier than the start), but may shrink to nothing in the extreme.

Timezone Options

All utilities that report time of day use the local timezone by default. The following timezone options are available:

`-z`
: Forces times to be reported in the timezone of the host that provided the metric values (the PCP collector host). When used in conjunction with `-a` and multiple archives, the convention is to use the timezone from the first named archive.

`-Z` *`timezone`*
: Sets the TZ variable to a timezone string, as defined in **environ(7)**, for example, `-Z UTC` for universal time.

PCP Environment Variables

When you are using PCP tools and utilities and are calling PCP library functions, a standard set of defined environment variables are available in the `${PCP_DIR}/etc/pcp.conf` file. These variables are generally used to specify the location of various PCP pieces in the file system and may be loaded into shell scripts by sourcing the `${PCP_DIR}/etc/pcp.env` shell script. They may also be queried by C, C++, perl and python programs using the **pmGetConfig** library function. If a variable is already defined in the environment, the values in the `pcp.conf` file do not override those values; that is, the values in `pcp.conf` serve only as installation defaults. For additional information, see the **pcp.conf(5)**, **pcp.env(5)**, and **pmGetConfig(3)** man pages.

The following environment variables are recognized by PCP (these definitions are also available on the **PCPIntro(1)** man page):

`PCP_COUNTER_WRAP`
: Many of the performance metrics exported from PCP agents expect that counters increase monotonically. Under some circumstances, one value of a metric may be smaller than the previously fetched value. This can happen when a counter of finite precision overflows, when the PCP agent has been reset or restarted, or when

	the PCP agent exports values from an underlying instrumentation that is subject to asynchronous discontinuity. If set, the PCP_COUNTER_WRAP environment variable indicates that all such cases of a decreasing counter should be treated as a counter overflow; and hence the values are assumed to have wrapped once in the interval between consecutive samples. Counter wrapping was the default in versions before the PCP release 1.3.
PCP_STDERR	Specifies whether **pmprintf()** error messages are sent to standard error, an pmconfirm dialog box, or to a named file; see the **pmprintf(3)** man page. Messages go to standard error if PCP_STDERR is unset or set without a value. If this variable is set to DISPLAY, then messages go to an pmconfirm dialog box; see the **pmconfirm(1)** man page. Otherwise, the value of PCP_STDERR is assumed to be the name of an output file.
PMCD_CONNECT_TIMEOUT	When attempting to connect to a remote PMCD on a system that is booting or at the other end of a slow network link, some PMAPI routines could potentially block for a long time until the remote system responds. These routines abort and return an error if the connection has not been established after some specified interval has elapsed. The default interval is 5 seconds. This may be modified by setting this variable in the environment to a larger number of seconds for the desired time out. This is most useful in cases where the remote host is at the end of a slow network, requiring longer latencies to establish the connection correctly.
PMCD_PORT	This TCP/IP port is used by PMCD to create the socket for incoming connections and requests. The default is port number 44321, which you may override by setting this variable to a different port number. If a non-default port is in effect when PMCD is started, then every monitoring application connecting to that PMCD must also have this variable set in its environment before attempting a connection.
PMCD_LOCAL	This setting indicates that PMCD must only bind to the loopback interface for incoming connections and requests. In this mode, connections from remote hosts are not possible.
PMCD_RECONNECT_TIMEOUT	When a monitor or client application loses its connection to a PMCD, the connection may be reestablished by calling the **pmReconnectContext(3)** PMAPI function.

	However, attempts to reconnect are controlled by a back-off strategy to avoid flooding the network with reconnection requests. By default, the back-off delays are 5, 10, 20, 40, and 80 seconds for consecutive reconnection requests from a client (the last delay is repeated for any further attempts after the last delay in the list). Setting this environment variable to a comma-separated list of positive integers redefines the back-off delays. For example, setting the delays to **1,2** will back off for 1 second, then back off every 2 seconds thereafter.
PMCD_REQUEST_TIMEOUT	For monitor or client applications connected to PMCD, there is a possibility of the application hanging on a request for performance metrics or metadata or help text. These delays may become severe if the system running PMCD crashes or the network connection is lost or the network link is very slow. By setting this environment variable to a real number of seconds, requests to PMCD timeout after the specified number of seconds. The default behavior is to wait 10 seconds for a response from every PMCD for all applications.
PMLOGGER_PORT	This environment variable may be used to change the base TCP/IP port number used by **pmlogger** to create the socket to which **pmlc** instances try to connect. The default base port number is 4330. If used, this variable should be set in the environment before **pmlogger** is executed. If **pmlc** and **pmlogger** are on different hosts, then obviously PMLOGGER_PORT must be set to the same value in both places.
PMLOGGER_LOCAL	This environment variable indicates that **pmlogger** must only bind to the loopback interface for **pmlc** connections and requests. In this mode, **pmlc** connections from remote hosts are not possible. If used, this variable should be set in the environment before **pmlogger** is executed.
PMPROXY_PORT	This environment variable may be used to change the base TCP/IP port number used by **pmproxy** to create the socket to which proxied clients connect, on their way to a distant **pmcd**.
PMPROXY_LOCAL	This setting indicates that **pmproxy** must only bind to the loopback interface for incoming connections and requests. In this mode, connections from remote hosts are not possible.

Running PCP Tools through a Firewall

In some production environments, the Performance Co-Pilot (PCP) monitoring hosts are on one side of a TCP/IP firewall, and the PCP collector hosts may be on the other side.

If the firewall service sits between the monitor and collector tools, the `pmproxy` service may be used to perform both packet forwarding and DNS proxying through the firewall; see the **pmproxy(1)** man page. Otherwise, it is necessary to arrange for packet forwarding to be enabled for those TCP/IP ports used by PCP, namely 44321 (or the value of the `PMCD_PORT` environment variable) for connections to PMCD.

The pmproxy service

The **pmproxy** service allows PCP clients running on hosts located on one side of a firewall to monitor remote hosts on the other side. The basic connection syntax is as follows, where *`tool`* is an arbitrary PCP application, typically a monitoring tool:

```
pmprobe -h remotehost@proxyhost
```

This extended host specification syntax is part of a larger set of available extensions to the basic host naming syntax - refer to the **PCPIntro(1)** man page for further details.

Transient Problems with Performance Metric Values

Sometimes the values for a performance metric as reported by a PCP tool appear to be incorrect. This is typically caused by transient conditions such as metric wraparound or time skew, described below. These conditions result from design decisions that are biased in favor of lightweight protocols and minimal resource demands for PCP components.

In all cases, these events are expected to occur infrequently, and should not persist beyond a few samples.

Performance Metric Wraparound

Performance metrics are usually expressed as numbers with finite precision. For metrics that are cumulative counters of events or resource consumption, the value of the metric may occasionally overflow the specified range and wraparound to zero.

Because the value of these counter metrics is computed from the rate of change with respect to the previous sample, this may result in a transient condition where the rate of change is an unknown value. If the `PCP_COUNTER_WRAP` environment variable is set, this condition is treated as an overflow, and speculative rate calculations are made. In either case, the correct rate calculation for the metric returns with the next sample.

Time Dilation and Time Skew

If a PMDA is tardy in returning results, or the PCP monitoring tool is connected to PMCD via a slow or congested network, an error might be introduced in rate calculations due to a difference between the time the metric was sampled and the time PMCD sends the result to the monitoring tool.

In practice, these errors are usually so small as to be insignificant, and the errors are self-correcting (not cumulative) over consecutive samples.

A related problem may occur when the system time is not synchronized between multiple hosts, and the time stamps for the results returned from PMCD reflect the skew in the system times. In this case, it is recommended that NTP (network time protocol) be used to keep the system clocks on the collector systems synchronized; for information on NTP refer to the **ntpd(1)** man page.

Chapter 4. Monitoring System Performance

Table of Contents

This chapter describes the performance monitoring tools available in Performance Co-Pilot (PCP). This product provides a group of commands and tools for measuring system performance. Each tool is described completely by its own man page. The man pages are accessible through the **man** command. For example, the man page for the tool **pmrep** is viewed by entering the following command:

```
man pmrep
```

The following major sections are covered in this chapter:

- the section called “The **pmstat** Command”, discusses **pmstat**, a utility that provides a periodic one-line summary of system performance.
- the section called “The **pmrep** Command”, discusses **pmrep**, a utility that shows the current values for named performance metrics.
- the section called “The **pmval** Command”, describes **pmval**, a utility that displays performance metrics in a textual format.
- the section called “The **pminfo** Command”, describes **pminfo**, a utility that displays information about performance metrics.
- the section called “The **pmstore** Command”, describes the use of the **pmstore** utility to arbitrarily set or reset selected performance metric values.

The following sections describe the various graphical and text-based PCP tools used to monitor local or remote system performance.

The pmstat Command

The **pmstat** command provides a periodic, one-line summary of system performance. This command is intended to monitor system performance at the highest level, after which other tools may be used for examining subsystems to observe potential performance problems in greater detail. After entering the **pmstat** command, you see output similar to the following, with successive lines appearing periodically:

```
pmstat
@ Thu Aug 15 09:25:56 2017
 loadavg                     memory      swap        io    system         cpu
   1 min   swpd   free   buff  cache   pi   po   bi   bo   in   cs  us  sy  id
```

```
    1.29 833960  5614m 144744 265824    0    0    0 1664  13K  23K   6   7  81
    1.51 833956  5607m 144744 265712    0    0    0 1664  13K  24K   5   7  83
    1.55 833956  5595m 145196 271908    0    0  14K 1056  13K  24K   7   7  74
```

An additional line of output is added every five seconds. The `-t` *`interval`* option may be used to vary the update interval (i.e. the sampling interval).

The output from **pmstat** is directed to standard output, and the columns in the report are interpreted as follows:

`loadavg` The 1-minute load average (runnable processes).

`memory` The swpd column indicates average swap space used during the interval (all columns reported in Kbytes unless otherwise indicated). The `free` column indicates average free memory during the interval. The `buff` column indicates average buffer memory in use during the interval. The `cache` column indicates average cached memory in use during the interval.

`swap` Reports the average number of pages that are paged-in (`pi`) and paged-out (`po`) per second during the interval. It is normal for the paged-in values to be non-zero, but the system is suffering memory stress if the paged-out values are non-zero over an extended period.

`io` The `bi` and `bo` columns indicate the average rate per second of block input and block output operations respectfully, during the interval. These rates are independent of the I/O block size. If the values become large, they are reported as thousands of operations per second (K suffix) or millions of operations per second (M suffix).

`system` Context switch rate (`cs`) and interrupt rate (`in`). Rates are expressed as average operations per second during the interval. Note that the interrupt rate is normally at least HZ (the clock interrupt rate, and `kernel.all.hz` metric) interrupts per second.

`cpu` Percentage of CPU time spent executing user code (`us`), system and interrupt code (`sy`), idle loop (`id`).

As with most PCP utilities, real-time metric, and archive logs are interchangeable.

For example, the following command uses a local system PCP archive log *`20170731`* and the timezone of the host (`smash`) from which performance metrics in the archive were collected:

```
pmstat -a ${PCP_LOG_DIR}/pmlogger/smash/20170731 -t 2hour -A 1hour -z
Note: timezone set to local timezone of host "smash"
@ Wed Jul 31 10:00:00 2017
 loadavg                     memory      swap        io    system         cpu
   1 min   swpd   free   buff  cache   pi   po   bi   bo   in   cs  us  sy  id
    3.90  24648  6234m 239176  2913m    ?    ?    ?    ?    ?    ?   ?   ?   ?
    1.72  24648  5273m 239320  2921m    0    0    4   86  11K  19K   5   5  84
    3.12  24648  5194m 241428  2969m    0    0    0   84  10K  19K   5   5  85
    1.97  24644  4945m 244004  3146m    0    0    0   84  10K  19K   5   5  84
    3.82  24640  4908m 244116  3147m    0    0    0   83  10K  18K   5   5  85
    3.38  24620  4860m 244116  3148m    0    0    0   83  10K  18K   5   4  85
    2.89  24600  4804m 244120  3149m    0    0    0   83  10K  18K   5   4  85
pmFetch: End of PCP archive log
```

For complete information on `pmstat` usage and command line options, see the **pmstat(1)** man page.

The pmrep Command

The **pmrep** command displays performance metrics in ASCII tables, suitable for export into databases or report generators. It is a flexible command. For example, the following command provides continuous memory statistics on a host named `surf`:

```
pmrep -p -h surf kernel.all.load kernel.all.pswitch
          k.a.load  k.a.load  k.a.load  k.a.pswitch
          1 minute  5 minute  15 minut
                                              count/s
10:41:37     0.160     0.170     0.180          N/A
10:41:38     0.160     0.170     0.180     1427.016
10:41:39     0.160     0.170     0.180     2129.040
10:41:40     0.160     0.170     0.180     5335.163
10:41:41     0.160     0.170     0.180      723.125
10:41:42     0.140     0.160     0.180      591.859
```

See the **pmrep(1)** man page for more information.

The pmval Command

The **pmval** command dumps the current values for the named performance metrics. For example, the following command reports the value of performance metric `proc.nprocs` once per second (by default), and produces output similar to this:

```
pmval proc.nprocs
metric:    proc.nprocs
host:      localhost
semantics: instantaneous value
units:     none
samples:   all
interval:  1.00 sec
         81
         81
         82
         81
```

In this example, the number of running processes was reported once per second.

Where the semantics of the underlying performance metrics indicate that it would be sensible, **pmval** reports the rate of change or resource utilization.

For example, the following command reports idle processor utilization for each of four CPUs on the remote host `dove`, each five seconds apart, producing output of this form:

```
pmval -h dove -t 5sec -s 4 kernel.percpu.cpu.idle
metric:    kernel.percpu.cpu.idle
host:      dove
semantics: cumulative counter (converting to rate)
units:     millisec (converting to time utilization)
samples:   4
interval:  5.00 sec

cpu:1.1.0.a cpu:1.1.0.c cpu:1.1.1.a cpu:1.1.1.c
```

```
    1.000       0.9998      0.9998      1.000
    1.000       0.9998      0.9998      1.000
    0.8989      0.9987      0.9997      0.9995
    0.9568      0.9998      0.9996      1.000
```

Similarly, the following command reports disk I/O read rate every minute for just the disk `/dev/disk1`, and produces output similar to the following:

```
pmval -t 1min -i disk1 disk.dev.read
metric:    disk.dev.read
host:      localhost
semantics: cumulative counter (converting to rate)
units:     count (converting to count / sec)
samples:   indefinite
interval:  60.00 sec
        disk1
         33.67
         48.71
         52.33
         11.33
         2.333
```

The `-r` flag may be used to suppress the rate calculation (for metrics with counter semantics) and display the raw values of the metrics.

In the example below, manipulation of the time within the archive is achieved by the exchange of time control messages between **pmval** and **pmtime**.

```
pmval -g -a ${PCP_LOG_DIR}/pmlogger/myserver/20170731 kernel.all.load
```

The **pmval** command is documented by the **pmval(1)** man page, and annotated examples of the use of **pmval** can be found in the *PCP Tutorials and Case Studies* companion document.

The pminfo Command

The **pminfo** command displays various types of information about performance metrics available through the Performance Co-Pilot (PCP) facilities.

The `-T` option is extremely useful; it provides help text about performance metrics:

```
pminfo -T mem.util.cached
mem.util.cached
Help:
Memory used by the page cache, including buffered file data.
This is in-memory cache for files read from the disk (the pagecache)
but doesn't include SwapCached.
```

The `-t` option displays the one-line help text associated with the selected metrics. The `-T` option prints more verbose help text.

Without any options, **pminfo** verifies that the specified metrics exist in the namespace, and echoes those names. Metrics may be specified as arguments to **pminfo** using their full metric names. For example, this command returns the following response:

```
pminfo hinv.ncpu network.interface.total.bytes
```

```
hinv.ncpu
network.interface.total.bytes
```

A group of related metrics in the namespace may also be specified. For example, to list all of the `hinv` metrics you would use this command:

```
pminfo hinv
hinv.physmem
hinv.pagesize
hinv.ncpu
hinv.ndisk
hinv.nfilesys
hinv.ninterface
hinv.nnode
hinv.machine
hinv.map.scsi
hinv.map.cpu_num
hinv.map.cpu_node
hinv.map.lvname
hinv.cpu.clock
hinv.cpu.vendor
hinv.cpu.model
hinv.cpu.stepping
hinv.cpu.cache
hinv.cpu.bogomips
```

If no metrics are specified, **pminfo** displays the entire collection of metrics. This can be useful for searching for metrics, when only part of the full name is known. For example, this command returns the following response:

```
pminfo | grep nfs
nfs.client.calls
nfs.client.reqs
nfs.server.calls
nfs.server.reqs
nfs3.client.calls
nfs3.client.reqs
nfs3.server.calls
nfs3.server.reqs
nfs4.client.calls
nfs4.client.reqs
nfs4.server.calls
nfs4.server.reqs
```

The `-d` option causes **pminfo** to display descriptive information about metrics (refer to the **pmLookupDesc(3)** man page for an explanation of this metadata information). The following command and response show use of the `-d` option:

```
pminfo -d proc.nprocs disk.dev.read filesys.free
proc.nprocs
    Data Type: 32-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
    Semantics: instant  Units: none

disk.dev.read
    Data Type: 32-bit unsigned int  InDom: 60.1 0xf000001
```

```
    Semantics: counter  Units: count

filesys.free
    Data Type: 64-bit unsigned int  InDom: 60.5 0xf000005
    Semantics: instant  Units: Kbyte
```

The `-l` option causes **pminfo** to display labels about metrics (refer to the **pmLookupLabels(3)** man page for an explanation of this metadata information). If the metric has an instance domain, the labels associated with each instance of the metric is printed. The following command and response show use of the `-l` option:

```
pminfo -l -h shard kernel.pernode.cpu.user
kernel.percpu.cpu.sys
    inst [0 or "cpu0"] labels {"agent":"linux","cpu":0,"device_type":"cpu","domain
    inst [1 or "cpu1"] labels {"agent":"linux","cpu":1,"device_type":"cpu","domain
    inst [2 or "cpu2"] labels {"agent":"linux","cpu":2,"device_type":"cpu","domain
    inst [3 or "cpu3"] labels {"agent":"linux","cpu":3,"device_type":"cpu","domain
    inst [4 or "cpu4"] labels {"agent":"linux","cpu":4,"device_type":"cpu","domain
    inst [5 or "cpu5"] labels {"agent":"linux","cpu":5,"device_type":"cpu","domain
    inst [6 or "cpu6"] labels {"agent":"linux","cpu":6,"device_type":"cpu","domain
    inst [7 or "cpu7"] labels {"agent":"linux","cpu":7,"device_type":"cpu","domain
```

The `-f` option to **pminfo** forces the current value of each named metric to be fetched and printed. In the example below, all metrics in the group `hinv` are selected:

```
pminfo -f hinv
hinv.physmem
    value 15701

hinv.pagesize
    value 16384

hinv.ncpu
    value 4

hinv.ndisk
    value 6

hinv.nfilesys
    value 2

hinv.ninterface
    value 8

hinv.nnode
    value 2

hinv.machine
    value "IP35"

hinv.map.cpu_num
    inst [0 or "cpu:1.1.0.a"] value 0
    inst [1 or "cpu:1.1.0.c"] value 1
    inst [2 or "cpu:1.1.1.a"] value 2
    inst [3 or "cpu:1.1.1.c"] value 3
```

```
hinv.map.cpu_node
    inst [0 or "node:1.1.0"] value "/dev/hw/module/001c01/slab/0/node"
    inst [1 or "node:1.1.1"] value "/dev/hw/module/001c01/slab/1/node"

hinv.cpu.clock
    inst [0 or "cpu:1.1.0.a"] value 800
    inst [1 or "cpu:1.1.0.c"] value 800
    inst [2 or "cpu:1.1.1.a"] value 800
    inst [3 or "cpu:1.1.1.c"] value 800

hinv.cpu.vendor
    inst [0 or "cpu:1.1.0.a"] value "GenuineIntel"
    inst [1 or "cpu:1.1.0.c"] value "GenuineIntel"
    inst [2 or "cpu:1.1.1.a"] value "GenuineIntel"
    inst [3 or "cpu:1.1.1.c"] value "GenuineIntel"

hinv.cpu.model
    inst [0 or "cpu:1.1.0.a"] value "0"
    inst [1 or "cpu:1.1.0.c"] value "0"
    inst [2 or "cpu:1.1.1.a"] value "0"
    inst [3 or "cpu:1.1.1.c"] value "0"

hinv.cpu.stepping
    inst [0 or "cpu:1.1.0.a"] value "6"
    inst [1 or "cpu:1.1.0.c"] value "6"
    inst [2 or "cpu:1.1.1.a"] value "6"
    inst [3 or "cpu:1.1.1.c"] value "6"

hinv.cpu.cache
    inst [0 or "cpu:1.1.0.a"] value 0
    inst [1 or "cpu:1.1.0.c"] value 0
    inst [2 or "cpu:1.1.1.a"] value 0
    inst [3 or "cpu:1.1.1.c"] value 0

hinv.cpu.bogomips
    inst [0 or "cpu:1.1.0.a"] value 1195.37
    inst [1 or "cpu:1.1.0.c"] value 1195.37
    inst [2 or "cpu:1.1.1.a"] value 1195.37
    inst [3 or "cpu:1.1.1.c"] value 1195.37
```

The `-h` option directs **pminfo** to retrieve information from the specified host. If the metric has an instance domain, the value associated with each instance of the metric is printed:

```
pminfo -h dove -f filesys.mountdir
filesys.mountdir
    inst [0 or "/dev/xscsi/pci00.01.0/target81/lun0/part3"] value "/"
    inst [1 or "/dev/xscsi/pci00.01.0/target81/lun0/part1"] value "/boot/efi"
```

The `-m` option prints the Performance Metric Identifiers (PMIDs) of the selected metrics. This is useful for finding out which PMDA supplies the metric. For example, the output below identifies the PMDA supporting domain 4 (the leftmost part of the PMID) as the one supplying information for the metric `environ.extrema.mintemp`:

```
pminfo -m environ.extrema.mintemp
```

```
environ.extrema.mintemp PMID: 4.0.3
```

The `-v` option verifies that metric definitions in the PMNS correspond with supported metrics, and checks that a value is available for the metric. Descriptions and values are fetched, but not printed. Only errors are reported.

Complete information on the **pminfo** command is found in the **pminfo(1)** man page. There are further examples of the use of **pminfo** in the *PCP Tutorials and Case Studies*.

The pmstore Command

From time to time you may wish to change the value of a particular metric. Some metrics are counters that may need to be reset, and some are simply control variables for agents that collect performance metrics. When you need to change the value of a metric for any reason, the command to use is **pmstore**.

Note

For obvious reasons, the ability to arbitrarily change the value of a performance metric is not supported. Rather, PCP collectors selectively allow some metrics to be modified in a very controlled fashion.

The basic syntax of the command is as follows:

```
pmstore metricname value
```

There are also command line flags to further specify the action. For example, the `-i` option restricts the change to one or more instances of the performance metric.

The *value* may be in one of several forms, according to the following rules:

1. If the metric has an integer type, then *value* should consist of an optional leading hyphen, followed either by decimal digits or “0x” and some hexadecimal digits; “0X” is also acceptable instead of “0x.”

2. If the metric has a floating point type, then *value* should be in the form of an integer (described above), a fixed point number, or a number in scientific notation.

3. If the metric has a string type, then *value* is interpreted as a literal string of ASCII characters.

4. If the metric has an aggregate type, then an attempt is made to interpret *value* as an integer, a floating point number, or a string. In the first two cases, the minimal word length encoding is used; for example, “123” would be interpreted as a four-byte aggregate, and “0x100000000” would be interpreted as an eight-byte aggregate.

The following example illustrates the use of **pmstore** to enable performance metrics collection in the `txmon` PMDA (see `${PCP_PMDAS_DIR}/txmon` for the source code of the txmon PMDA). When the metric `txmon.control.level` has the value 0, no performance metrics are collected. Values greater than 0 enable progressively more verbose instrumentation.

```
pminfo -f txmon.count
txmon.count
No value(s) available!
pmstore txmon.control.level 1
txmon.control.level old value=0 new value=1
pminfo -f txmon.count
txmon.count
```

```
inst [0 or "ord-entry"] value 23
inst [1 or "ord-enq"] value 11
inst [2 or "ord-ship"] value 10
inst [3 or "part-recv"] value 3
inst [4 or "part-enq"] value 2
inst [5 or "part-used"] value 1
inst [6 or "b-o-m"] value 0
```

For complete information on **pmstore** usage and syntax, see the **pmstore(1)** man page.

Chapter 5. Performance Metrics Inference Engine

Table of Contents

The Performance Metrics Inference Engine (**pmie**) is a tool that provides automated monitoring of, and reasoning about, system performance within the Performance Co-Pilot (PCP) framework.

The major sections in this chapter are as follows:

- the section called “Introduction to **pmie**”, provides an introduction to the concepts and design of **pmie**.
- the section called “Basic **pmie** Usage”, describes the basic syntax and usage of **pmie**.
- the section called “Specification Language for **pmie**”, discusses the complete **pmie** rule specification language.
- the section called “**pmie** Examples”, provides an example, covering several common performance scenarios.
- the section called “Developing and Debugging **pmie** Rules”, presents some tips and techniques for **pmie** rule development.
- the section called “Caveats and Notes on **pmie**”, presents some important information on using **pmie**.

- the section called “Creating **pmie** Rules with **pmieconf**”, describes how to use the **pmieconf** command to generate **pmie** rules.
- the section called “Management of **pmie** Processes”, provides support for running **pmie** as a daemon.

Introduction to pmie

Automated reasoning within Performance Co-Pilot (PCP) is provided by the Performance Metrics Inference Engine, (**pmie**), which is an applied artificial intelligence application.

The **pmie** tool accepts expressions describing adverse performance scenarios, and periodically evaluates these against streams of performance metric values from one or more sources. When an expression is found to be true, **pmie** is able to execute arbitrary actions to alert or notify the system administrator of the occurrence of an adverse performance scenario. These facilities are very general, and are designed to accommodate the automated execution of a mixture of generic and site-specific performance monitoring and control functions.

The stream of performance metrics to be evaluated may be from one or more hosts, or from one or more PCP archive logs. In the latter case, **pmie** may be used to retrospectively identify adverse performance conditions.

Using **pmie**, you can filter, interpret, and reason about the large volume of performance data made available from PCP collector systems or PCP archives.

Typical **pmie** uses include the following:

- Automated real-time monitoring of a host, a set of hosts, or client-server pairs of hosts to raise operational alarms when poor performance is detected in a production environment
- Nightly processing of archive logs to detect and report performance regressions, or quantify quality of service for service level agreements or management reports, or produce advance warning of pending performance problems
- Strategic performance management, for example, detection of slightly abnormal to chronic system behavior, trend analysis, and capacity planning

The **pmie** expressions are described in a language with expressive power and operational flexibility. It includes the following operators and functions:

- Generalized predicate-action pairs, where a predicate is a logical expression over the available performance metrics, and the action is arbitrary. Predefined actions include the following:
  - Launch a visible alarm with `pmconfirm`; see the **pmconfirm(1)** man page.
  - Post an entry to the system log file; see the **syslog(3)** man page.
  - Post an entry to the PCP noticeboard file `${PCP_LOG_DIR}/NOTICES`; see the **pmpost(1)** man page.
  - Execute a shell command or script, for example, to send e-mail, initiate a pager call, warn the help desk, and so on.
  - Echo a message on standard output; useful for scripts that generate reports from retrospective processing of PCP archive logs.
- Arithmetic and logical expressions in a C-like syntax.

- Expression groups may have an independent evaluation frequency, to support both short-term and long-term monitoring.
- Canonical scale and rate conversion of performance metric values to provide sensible expression evaluation.
- Aggregation functions of `sum`, `avg`, `min`, and `max`, that may be applied to collections of performance metrics values clustered over multiple hosts, or multiple instances, or multiple consecutive samples in time.
- Universal and existential quantification, to handle expressions of the form “for every....” and “at least one...”.
- Percentile aggregation to handle statistical outliers, such as “for at least 80% of the last 20 samples, ...”.
- Macro processing to expedite repeated use of common subexpressions or specification components.
- Transparent operation against either live-feeds of performance metric values from PMCD on one or more hosts, or against PCP archive logs of previously accumulated performance metric values.

The power of **pmie** may be harnessed to automate the most common of the deterministic system management functions that are responses to changes in system performance. For example, disable a batch stream if the DBMS transaction commit response time at the ninetieth percentile goes over two seconds, or stop accepting uploads and send e-mail to the *`sysadmin`* alias if free space in a storage system falls below five percent.

Moreover, the power of **pmie** can be directed towards the exceptional and sporadic performance problems. For example, if a network packet storm is expected, enable IP header tracing for ten seconds, and send e-mail to advise that data has been collected and is awaiting analysis. Or, if production batch throughput falls below 50 jobs per minute, activate a pager to the systems administrator on duty.

Obviously, **pmie** customization is required to produce meaningful filtering and actions in each production environment. The **pmieconf** tool provides a convenient customization method, allowing the user to generate parameterized **pmie** rules for some of the more common performance scenarios.

Basic pmie Usage

This section presents and explains some basic examples of **pmie** usage. The **pmie** tool accepts the common PCP command line arguments, as described in Chapter 3, *Common Conventions and Arguments*. In addition, **pmie** accepts the following command line arguments:

`-d` Enables interactive debug mode.

`-v` Verbose mode: expression values are displayed.

`-V` Verbose mode: annotated expression values are displayed.

`-W` When-verbose mode: when a condition is true, the satisfying expression bindings are displayed.

One of the most basic invocations of this tool is this form:

`pmie` *`filename`*

In this form, the expressions to be evaluated are read from *filename*. In the absence of a given *filename*, expressions are read from standard input, which may be your system keyboard.

pmie use of PCP services

Before you use **pmie**, it is strongly recommended that you familiarize yourself with the concepts from the the section called “Conceptual Foundations”. The discussion in this section serves as a very brief review of these concepts.

PCP makes available thousands of performance metrics that you can use when formulating expressions for **pmie** to evaluate. If you want to find out which metrics are currently available on your system, use this command:

pminfo

Use the **pmie** command line arguments to find out more about a particular metric. In Example 5.1, “**pmie** with the `-f` Option”, to fetch new metric values from host `dove`, you use the `-f` flag:

Example 5.1. pmie with the `-f` Option

pminfo -f -h dove disk.dev.total

This produces the following response:

```
disk.dev.total
    inst [0 or "xscsi/pci00.01.0/target81/lun0/disc"] value 131233
    inst [4 or "xscsi/pci00.01.0/target82/lun0/disc"] value 4
    inst [8 or "xscsi/pci00.01.0/target83/lun0/disc"] value 4
    inst [12 or "xscsi/pci00.01.0/target84/lun0/disc"] value 4
    inst [16 or "xscsi/pci00.01.0/target85/lun0/disc"] value 4
    inst [18 or "xscsi/pci00.01.0/target86/lun0/disc"] value 4
```

This reveals that on the host `dove`, the metric `disk.dev.total` has six instances, one for each disk on the system.

Use the following command to request help text (specified with the `-T` flag) to provide more information about performance metrics:

pminfo -T network.interface.in.packets

The metadata associated with a performance metric is used by **pmie** to determine how the value should be interpreted. You can examine the descriptor that encodes the metadata by using the `-d` flag for **pminfo**, as shown in Example 5.2, “**pmie** with the `-d` and `-h` Options”:

Example 5.2. pmie with the `-d` and `-h` Options

pminfo -d -h *somehost* **mem.util.cached kernel.percpu.cpu.user**

In response, you see output similar to this:

```
mem.util.cached
    Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
    Semantics: instant  Units: Kbyte

kernel.percpu.cpu.user
    Data Type: 64-bit unsigned int  InDom: 60.0 0xf000000
```

```
 Semantics: counter  Units: millisec
```

Note

A cumulative counter such as `kernel.percpu.cpu.user` is automatically converted by **pmie** into a rate (measured in events per second, or count/second), while instantaneous values such as `mem.util.cached` are not subjected to rate conversion. Metrics with an instance domain (`InDom` in the **pminfo** output) of `PM_INDOM_NULL` are singular and always produce one value per source. However, a metric like `kernel.percpu.cpu.user` has an instance domain, and may produce multiple values per source (in this case, it is one value for each configured CPU).

Simple pmie Usage

Example 5.3, "**pmie** with the `-v` Option" directs the inference engine to evaluate and print values (specified with the `-v` flag) for a single performance metric (the simplest possible expression), in this case `disk.dev.total`, collected from the local PMCD:

Example 5.3. pmie with the `-v` Option

```
pmie -v
iops = disk.dev.total;
Ctrl+D
iops:      ?      ?
iops:   14.4      0
iops:   25.9  0.112
iops:   12.2      0
iops:   12.3   64.1
iops:  8.594  52.17
iops:  2.001  71.64
```

On this system, there are two disk spindles, hence two values of the expression **iops** per sample. Notice that the values for the first sample are unknown (represented by the question marks [?] in the first line of output), because rates can be computed only when at least two samples are available. The subsequent samples are produced every ten seconds by default. The second sample reports that during the preceding ten seconds there was an average of 14.4 transfers per second on one disk and no transfers on the other disk.

Rates are computed using time stamps delivered by PMCD. Due to unavoidable inaccuracy in the actual sampling time (the sample interval is not exactly 10 seconds), you may see more decimal places in values than you expect. Notice, however, that these errors do not accumulate but cancel each other out over subsequent samples.

In Example 5.3, "**pmie** with the `-v` Option", the expression to be evaluated was entered using the keyboard, followed by the end-of-file character [**Ctrl**+**D**]. Usually, it is more convenient to enter expressions into a file (for example, `myrules`) and ask **pmie** to read the file. Use this command syntax:

```
pmie -v myrules
```

Please refer to the **pmie(1)** man page for a complete description of **pmie** command line options.

Complex pmie Examples

This section illustrates more complex **pmie** expressions of the specification language. the section called "Specification Language for **pmie**", provides a complete description of the **pmie** specification language.

The following arithmetic expression computes the percentage of write operations over the total number of disk transfers.

```
(disk.all.write / disk.all.total) * 100;
```

The `disk.all` metrics are singular, so this expression produces exactly one value per sample, independent of the number of disk devices.

Note

If there is no disk activity, `disk.all.total` will be zero and **pmie** evaluates this expression to be not a number. When `-v` is used, any such values are displayed as question marks.

The following logical expression has the value `true` or `false` for each disk:

```
disk.dev.total > 10 &&
disk.dev.write > disk.dev.read;
```

The value is true if the number of writes exceeds the number of reads, and if there is significant disk activity (more than 10 transfers per second). Example 5.4, “Printed **pmie** Output” demonstrates a simple action:

Example 5.4. Printed pmie Output

```
some_inst disk.dev.total > 60
          -> print "[%i] high disk i/o";
```

This prints a message to the standard output whenever the total number of transfers for some disk (`some_inst`) exceeds 60 transfers per second. The `%i` (instance) in the message is replaced with the name(s) of the disk(s) that caused the logical expression to be `true`.

Using **pmie** to evaluate the above expressions every 3 seconds, you see output similar to Example 5.5, “Labelled **pmie** Output”. Notice the introduction of labels for each **pmie** expression.

Example 5.5. Labelled pmie Output

```
pmie -v -t 3sec
pct_wrt = (disk.all.write / disk.all.total) * 100;
busy_wrt = disk.dev.total > 10 &&
          disk.dev.write > disk.dev.read;
busy = some_inst disk.dev.total > 60
          -> print "[%i] high disk i/o ";
Ctrl+D
pct_wrt:       ?
busy_wrt:      ?      ?
busy:          ?

pct_wrt:   18.43
busy_wrt:  false  false
busy:      false

Mon Aug  5 14:56:08 2012: [disk2] high disk i/o
pct_wrt:   10.83
busy_wrt:  false  false
busy:      true
```

```
pct_wrt:   19.85
busy_wrt:   true  false
busy:      false

pct_wrt:       ?
busy_wrt:  false  false
busy:      false

Mon Aug  5 14:56:17 2012: [disk1] high disk i/o [disk2] high disk i/o
pct_wrt:   14.8
busy_wrt:  false  false
busy:   true
```

The first sample contains unknowns, since all expressions depend on computing rates. Also notice that the expression `pct_wrt` may have an undefined value whenever all disks are idle, as the denominator of the expression is zero. If one or more disks is busy, the expression `busy` is true, and the message from the `print` in the action part of the rule appears (before the `-v` values).

Specification Language for pmie

This section describes the complete syntax of the **pmie** specification language, as well as macro facilities and the issue of sampling and evaluation frequency. The reader with a preference for learning by example may choose to skip this section and go straight to the examples in the section called "**pmie** Examples".

Complex expressions are built up recursively from simple elements:

1. Performance metric values are obtained from PMCD for real-time sources, otherwise from PCP archive logs.

2. Metrics values may be combined using arithmetic operators to produce arithmetic expressions.

3. Arithmetic expressions may be compared using relational operators to produce logical expressions.

4. Logical expressions may be combined using Boolean operators, including powerful quantifiers.

5. Aggregation operators may be used to compute summary expressions, for either arithmetic or logical operands.

6. The final logical expression may be used to initiate a sequence of actions.

Basic pmie Syntax

The **pmie** rule specification language supports a number of basic syntactic elements.

Lexical Elements

All **pmie** expressions are composed of the following lexical elements:

Identifier

Begins with an alphabetic character (either upper or lowercase), followed by zero or more letters, the numeric digits, and the special characters period (`.`) and underscore (_), as shown in the following example:

```
x, disk.dev.total and my_stuff
```

	As a special case, an arbitrary sequence of letters enclosed by apostrophes (') is also interpreted as an *identifier*; for example: `'vms$slow_response'`
Keyword	The aggregate operators, units, and predefined actions are represented by keywords; for example, `some_inst`, `print`, and `hour`.
Numeric constant	Any likely representation of a decimal integer or floating point number; for example, 124, 0.05, and -45.67
String constant	An arbitrary sequence of characters, enclosed by double quotation marks (`"x"`).

Within quotes of any sort, the backslash (\) may be used as an escape character as shown in the following example:

```
"A \"gentle\" reminder"
```

Comments

Comments may be embedded anywhere in the source, in either of these forms:

`/* text */`	Comment, optionally spanning multiple lines, with no nesting of comments.
`// text`	Comment from here to the end of the line.

Macros

When they are fully specified, expressions in **pmie** tend to be verbose and repetitive. The use of macros can reduce repetition and improve readability and modularity. Any statement of the following form associates the macro name `identifier` with the given string constant.

```
identifier = "string";
```

Any subsequent occurrence of the macro name `identifier` is replaced by the *string* most recently associated with a macro definition for `identifier`.

```
$identifier
```

For example, start with the following macro definition:

```
disk = "disk.all";
```

You can then use the following syntax:

```
pct_wrt = ($disk.write / $disk.total) * 100;
```

Note

Macro expansion is performed before syntactic parsing; so macros may only be assigned constant string values.

Units

The inference engine converts all numeric values to canonical units (seconds for time, bytes for space, and events for count). To avoid surprises, you are encouraged to specify the units for numeric constants. If units are specified, they are checked for dimension compatibility against the metadata for the associated performance metrics.

The syntax for a `units` specification is a sequence of one or more of the following keywords separated by either a space or a slash (`/`), to denote per: `byte`, `KByte`, `MByte`, `GByte`, `TByte`, `nsec`, `nanosecond`, `usec`, `microsecond`, `msec`, `millisecond`, `sec`, `second`, `min`, `minute`, `hour`, `count`, `Kcount`, `Mcount`, `Gcount`, or `Tcount`. Plural forms are also accepted.

The following are examples of units usage:

```
disk.dev.blktotal > 1 Mbyte / second;
mem.util.cached < 500 Kbyte;
```

Note

If you do not specify the units for numeric constants, it is assumed that the constant is in the canonical units of seconds for time, bytes for space, and events for count, and the dimensionality of the constant is assumed to be correct. Thus, in the following expression, the `500` is interpreted as 500 bytes.

```
mem.util.cached < 500
```

Setting Evaluation Frequency

The identifier name `delta` is reserved to denote the interval of time between consecutive evaluations of one or more expressions. Set `delta` as follows:

```
delta = number [units];
```

If present, `units` must be one of the time units described in the preceding section. If absent, `units` are assumed to be `seconds`. For example, the following expression has the effect that any subsequent expressions (up to the next expression that assigns a value to `delta`) are scheduled for evaluation at a fixed frequency, once every five minutes.

```
delta = 5 min;
```

The default value for `delta` may be specified using the `-t` command line option; otherwise `delta` is initially set to be 10 seconds.

pmie Metric Expressions

The performance metrics namespace (PMNS) provides a means of naming performance metrics, for example, `disk.dev.read`. PCP allows an application to retrieve one or more values for a performance metric from a designated source (a collector host running PMCD, or a set of PCP archive logs). To specify a single value for some performance metric requires the metric name to be associated with all three of the following:

- A particular host (or source of metrics values)
- A particular instance (for metrics with multiple values)

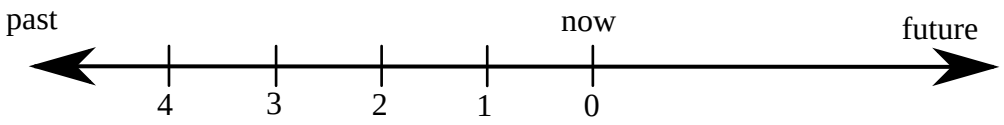
- A sample time

The permissible values for hosts are the range of valid hostnames as provided by Internet naming conventions.

The names for instances are provided by the Performance Metrics Domain Agents (PMDA) for the instance domain associated with the chosen performance metric.

The sample time specification is defined as the set of natural numbers 0, 1, 2, and so on. A number refers to one of a sequence of sampling events, from the current sample 0 to its predecessor 1, whose predecessor was 2, and so on. This scheme is illustrated by the time line shown in Figure 5.1, “Sampling Time Line”.

Figure 5.1. Sampling Time Line



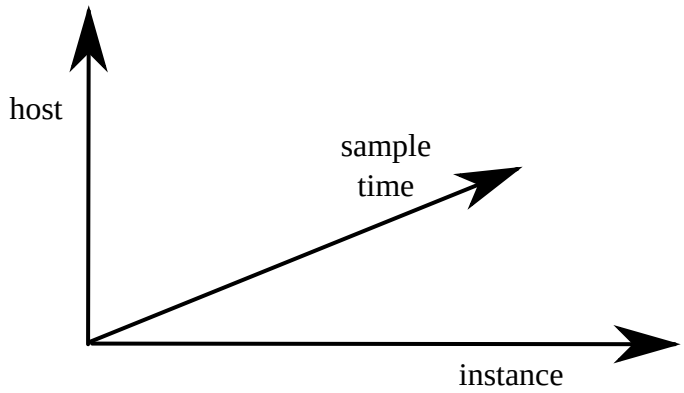
Each sample point is assumed to be separated from its predecessor by a constant amount of real time, the `delta`. The most recent sample point is always zero. The value of `delta` may vary from one expression to the next, but is fixed for each expression; for more information on the sampling interval, see the section called “Setting Evaluation Frequency”.

For **pmie**, a metrics expression is the name of a metric, optionally qualified by a host, instance and sample time specification. Special characters introduce the qualifiers: colon (`:`) for hosts, hash or pound sign (#) for instances, and at (@) for sample times. The following expression refers to the previous value (`@1`) of the counter for the disk read operations associated with the disk instance `#disk1` on the host `moomba`.

```
disk.dev.read :moomba #disk1 @1
```

In fact, this expression defines a point in the three-dimensional (3D) parameter space of {`host`} x {`instance`} x {`sample time`} as shown in Figure 5.2, “Three-Dimensional Parameter Space”.

Figure 5.2. Three-Dimensional Parameter Space



A metric expression may also identify sets of values corresponding to one-, two-, or three-dimensional slices of this space, according to the following rules:

1. A metric expression consists of a PCP metric name, followed by optional host specifications, followed by optional instance specifications, and finally, optional sample time specifications.

2. A host specification consists of one or more host names, each prefixed by a colon (`:`). For example: `:indy :far.away.domain.com :localhost`

3. A missing host specification implies the default **pmie** source of metrics, as defined by a `-h` option on the command line, or the first named archive in an `-a` option on the command line, or PMCD on the local host.

4. An instance specification consists of one or more instance names, each prefixed by a hash or pound (#) sign. For example: `#eth0 #eth2`

   Recall that you can discover the instance names for a particular metric, using the **pminfo** command. See the section called "**pmie** use of PCP services".

   Within the **pmie** grammar, an instance name is an identifier. If the instance name contains characters other than alphanumeric characters, enclose the instance name in single quotes; for example, `#'/boot' #'/usr'`

5. A missing instance specification implies all instances for the associated performance metric from each associated **pmie** source of metrics.

6. A sample time specification consists of either a single time or a range of times. A single time is represented as an at (@) followed by a natural number. A range of times is an at (@), followed by a natural number, followed by two periods (`..`) followed by a second natural number. The ordering of the end points in a range is immaterial. For example, `@0..9` specifies the last 10 sample times.

7. A missing sample time specification implies the most recent sample time.

The following metric expression refers to a three-dimensional set of values, with two hosts in one dimension, five sample times in another, and the number of instances in the third dimension being determined by the number of configured disk spindles on the two hosts.

```
disk.dev.read :foo :bar @0..4
```

pmie Rate Conversion

Many of the metrics delivered by PCP are cumulative counters. Consider the following metric:

```
disk.all.total
```

A single value for this metric tells you only that a certain number of disk I/O operations have occurred since boot time, and that information may be invalid if the counter has exceeded its 32-bit range and wrapped. You need at least two values, sampled at known times, to compute the recent rate at which the I/O operations are being executed. The required syntax would be this:

```
(disk.all.total @0 - disk.all.total @1) / delta
```

The accuracy of `delta` as a measure of actual inter-sample delay is an issue. **pmie** requests samples, at intervals of approximately `delta`, while the results exported from PMCD are time stamped with the high-resolution system clock time when the samples were extracted. For these reasons, a built-in and implicit rate conversion using accurate time stamps is provided by **pmie** for performance metrics that have counter semantics. For example, the following expression is unconditionally converted to a rate by **pmie**.

```
disk.all.total
```

pmie Arithmetic Expressions

Within **pmie**, simple arithmetic expressions are constructed from metrics expressions (see the section called "**pmie** Metric Expressions") and numeric constants, using all of the arithmetic operators and precedence rules of the C programming language.

All **pmie** arithmetic is performed in double precision.

the section called "**pmie** Intrinsic Operators", describes additional operators that may be used for aggregate operations to reduce the dimensionality of an arithmetic expression.

pmie Logical Expressions

A number of logical expression types are supported:

- Logical constants
- Relational expressions
- Boolean expressions
- Quantification operators

Logical Constants

Like in the C programming language, **pmie** interprets an arithmetic value of zero to be false, and all other arithmetic values are considered true.

Relational Expressions

Relational expressions are the simplest form of logical expression, in which values may be derived from arithmetic expressions using **pmie** relational operators. For example, the following is a relational expression that is true or false, depending on the aggregate total of disk read operations per second being greater than 50.

```
disk.all.read > 50 count/sec
```

All of the relational logical operators and precedence rules of the C programming language are supported in **pmie**.

As described in the section called "**pmie** Metric Expressions", arithmetic expressions in **pmie** may assume set values. The relational operators are also required to take constant, singleton, and set-valued expressions as arguments. The result has the same dimensionality as the operands. Suppose the rule in Example 5.6, "Relational Expressions " is given:

Example 5.6. Relational Expressions

```
hosts = ":gonzo";
intfs = "#eth0 #eth2";
all_intf = network.interface.in.packets
               $hosts $intfs @0..2 > 300 count/sec;
```

Then the execution of **pmie** may proceed as follows:

```
pmie -V uag.11
```

```
all_intf:
       gonzo: [eth0]      ?      ?      ?
       gonzo: [eth2]      ?      ?      ?
all_intf:
       gonzo: [eth0]  false      ?      ?
       gonzo: [eth2]  false      ?      ?
all_intf:
       gonzo: [eth0]   true  false      ?
       gonzo: [eth2]  false  false      ?
all_intf:
       gonzo: [eth0]   true   true  false
       gonzo: [eth2]  false  false  false
```

At each sample, the relational operator greater than (>) produces six truth values for the cross-product of the `instance` and `sample time` dimensions.

the section called “Quantification Operators”, describes additional logical operators that may be used to reduce the dimensionality of a relational expression.

Boolean Expressions

The regular Boolean operators from the C programming language are supported: conjunction (&&), disjunction (||) and negation (!).

As with the relational operators, the Boolean operators accommodate set-valued operands, and set-valued results.

Quantification Operators

Boolean and relational operators may accept set-valued operands and produce set-valued results. In many cases, rules that are appropriate for performance management require a set of truth values to be reduced along one or more of the dimensions of hosts, instances, and sample times described in the section called “**pmie** Metric Expressions”. The **pmie** quantification operators perform this function.

Each quantification operator takes a one-, two-, or three-dimension set of truth values as an operand, and reduces it to a set of smaller dimension, by quantification along a single dimension. For example, suppose the expression in the previous example is simplified and prefixed by `some_sample`, to produce the following expression:

```
intfs = "#eth0 #eth2";
all_intf = some_sample network.interface.in.packets
                    $intfs @0..2 > 300 count/sec;
```

Then the expression result is reduced from six values to two (one per interface instance), such that the result for a particular instance will be false unless the relational expression for the same interface instance is true for at least one of the preceding three sample times.

There are existential, universal, and percentile quantification operators in each of the *`host`*, *`instance`*, and *`sample time`* dimensions to produce the nine operators as follows:

`some_host` — True if the expression is true for at least one *`host`* for the same *`instance`* and `sample time`.

`all_host` — True if the expression is true for every *`host`* for the same *`instance`* and *`sample time`*.

N%_host	True if the expression is true for at least *N*% of the *hosts* for the same *instance* and *sample time*.
some_inst	True if the expression is true for at least one *instance* for the same *host* and *sample time*.
all_instance	True if the expression is true for every *instance* for the same *host* and *sample time*.
N%_instance	True if the expression is true for at least *N*% of the *instances* for the same *host* and *sample time*.
some_sample time	True if the expression is true for at least one *sample time* for the same *host* and *instance*.
all_sample time	True if the expression is true for every *sample time* for the same *host* and *instance*.
N%_sample time	True if the expression is true for at least *N*% of the *sample times* for the same *host* and *instance*.

These operators may be nested. For example, the following expression answers the question: “Are all hosts experiencing at least 20% of their disks busy either reading or writing?”

```
Servers = ":moomba :babylon";
all_host (
    20%_inst disk.dev.read $Servers > 40 ||
    20%_inst disk.dev.write $Servers > 40
);
```

The following expression uses different syntax to encode the same semantics:

```
all_host (
    20%_inst (
        disk.dev.read $Servers > 40 ||
        disk.dev.write $Servers > 40
    )
);
```

Note

To avoid confusion over precedence and scope for the quantification operators, use explicit parentheses.

Two additional quantification operators are available for the instance dimension only, namely match_inst and nomatch_inst, that take a regular expression and a boolean expression. The result is the boolean AND of the expression and the result of matching (or not matching) the associated instance name against the regular expression.

For example, this rule evaluates error rates on various 10BaseT Ethernet network interfaces (such as ecN, ethN, or efN):

```
some_inst
        match_inst "^(ec|eth|ef)"
                network.interface.total.errors > 10 count/sec
-> syslog "Ethernet errors:" " %i"
```

pmie Rule Expressions

Rule expressions for **pmie** have the following syntax:

```
lexpr -> actions ;
```

The semantics are as follows:

- If the logical expression `lexpr` evaluates `true`, then perform the *`actions`* that follow. Otherwise, do not perform the *`actions`*.
- It is required that `lexpr` has a singular truth value. Aggregation and quantification operators must have been applied to reduce multiple truth values to a single value.
- When executed, an *`action`* completes with a success/failure status.
- One or more *`actions`* may appear; consecutive *`actions`* are separated by operators that control the execution of subsequent *`actions`*, as follows:

  `action-1` **`&`** Always execute subsequent actions (serial execution).

  `action-1` **`|`** If *`action-1`* fails, execute subsequent actions, otherwise skip the subsequent actions (alternation).

An *`action`* is composed of a keyword to identify the action method, an optional *`time`* specification, and one or more arguments.

A *`time`* specification uses the same syntax as a valid time interval that may be assigned to `delta`, as described in the section called “Setting Evaluation Frequency”. If the *`action`* is executed and the *`time`* specification is present, **pmie** will suppress any subsequent execution of this *`action`* until the wall clock time has advanced by *`time`*.

The arguments are passed directly to the action method.

The following action methods are provided:

`shell` The single argument is passed to the shell for execution. This *`action`* is implemented using `system` in the background. The *`action`* does not wait for the system call to return, and succeeds unless the fork fails.

`alarm` A notifier containing a time stamp, a single *`argument`* as a message, and a Cancel button is posted on the current display screen (as identified by the `DISPLAY` environment variable). Each alarm *`action`* first checks if its notifier is already active. If there is an identical active notifier, a duplicate notifier is not posted. The action succeeds unless the fork fails.

`syslog` A message is written into the system log. If the first word of the first argument is `-p`, the second word is interpreted as the priority (see the **syslog(3)** man page); the message tag is `pcp-pmie`. The remaining argument is the message to be written to the system log. This action always succeeds.

`print` A message containing a time stamp in **ctime(3)** format and the argument is displayed out to standard output (**stdout**). This action always succeeds.

Within the argument passed to an action method, the following expansions are supported to allow some of the context from the logical expression on the left to appear to be embedded in the argument:

`%h` The value of a *`host`* that makes the expression true.

`%i` The value of an *`instance`* that makes the expression true.

`%v` The value of a performance metric from the logical expression.

Some ambiguity may occur in respect to which host, instance, or performance metric is bound to a %-token. In most cases, the leftmost binding in the top-level subexpression is used. You may need to use **pmie** in the interactive debugging mode (specify the `-d` command line option) in conjunction with the `-W` command line option to discover which subexpressions contributes to the %-token bindings.

Example 5.7, “Rule Expression Options ” illustrates some of the options when constructing rule expressions:

Example 5.7. Rule Expression Options

```
some_inst ( disk.dev.total > 60 )
       -> syslog 10 mins "[%i] busy, %v IOPS " &
          shell 1 hour "echo \
               'Disk %i is REALLY busy. Running at %v I/Os per second' \
               | Mail -s 'pmie alarm' sysadm";
```

In this case, `%v` and `%i` are both associated with the instances for the metric `disk.dev.total` that make the expression true. If more than one instance makes the expression true (more than one disk is busy), then the argument is formed by concatenating the result from each %-token binding. The text added to the system log file might be as shown in Example 5.8, “System Log Text”:

Example 5.8. System Log Text

```
Aug 6 08:12:44 5B:gonzo pcp-pmie[3371]:
                         [disk1] busy, 3.7 IOPS [disk2] busy, 0.3 IOPS
```

Note

When **pmie** is processing performance metrics from a set of PCP archive logs, the *`actions`* will be processed in the expected manner; however, the action methods are modified to report a textual facsimile of the *`action`* on the standard output.

Consider the rule in Example 5.9, “Standard Output”:

Example 5.9. Standard Output

```
delta = 2 sec;  // more often for demonstration purposes
percpu  = "kernel.percpu";
// Unusual usr-sys split when some CPU is more than 20% in usr mode
// and sys mode is at least 1.5 times usr mode
//
cpu_usr_sys = some_inst (
        $percpu.cpu.sys > $percpu.cpu.user * 1.5 &&
        $percpu.cpu.user > 0.2
   ) ->  alarm "Unusual sys time: " "%i ";
```

When evaluated against an archive, the following output is generated (the alarm action produces a message on standard output):

```
pmafm ${HOME}/f4 pmie cpu.head cpu.00
```

```
alarm Wed Aug  7 14:54:48 2012: Unusual sys time: cpu0
alarm Wed Aug  7 14:54:50 2012: Unusual sys time: cpu0
alarm Wed Aug  7 14:54:52 2012: Unusual sys time: cpu0
alarm Wed Aug  7 14:55:02 2012: Unusual sys time: cpu0
alarm Wed Aug  7 14:55:06 2012: Unusual sys time: cpu0
```

pmie Intrinsic Operators

The following sections describe some other useful intrinsic operators for **pmie**. These operators are divided into three groups:

- Arithmetic aggregation
- The `rate` operator
- Transitional operators

Arithmetic Aggregation

For set-valued arithmetic expressions, the following operators reduce the dimensionality of the result by arithmetic aggregation along one of the *`host`*, *`instance`*, or *`sample time`* dimensions. For example, to aggregate in the *`host`* dimension, the following operators are provided:

`avg_host` Computes the average value across all *`instances`* for the same *`host`* and *`sample time`*

`sum_host` Computes the total value across all *`instances`* for the same *`host`* and *`sample time`*

`count_host` Computes the number of values across all *`instances`* for the same *`host`* and *`sample time`*

`min_host` Computes the minimum value across all *`instances`* for the same *`host`* and *`sample time`*

`max_host` Computes the maximum value across all *`instances`* for the same *`host`* and *`sample time`*

Ten additional operators correspond to the forms `*_inst` and `*_sample`.

The following example illustrates the use of an aggregate operator in combination with an existential operator to answer the question “Does some host currently have two or more busy processors?”

```
// note '' to escape - in host name
poke = ":moomba :'mac-larry' :bitbucket";
some_host (
    count_inst ( kernel.percpu.cpu.user $poke +
                 kernel.percpu.cpu.sys $poke > 0.7 ) >= 2
    )
       -> alarm "2 or more busy CPUs";
```

The rate Operator

The `rate` operator computes the rate of change of an arithmetic expression as shown in the following example:

```
rate mem.util.cached
```

It returns the rate of change for the `mem.util.cached` performance metric; that is, the rate at which page cache memory is being allocated and released.

The `rate` intrinsic operator is most useful for metrics with instantaneous value semantics. For metrics with counter semantics, **pmie** already performs an implicit rate calculation (see the the section called "**pmie** Rate Conversion") and the `rate` operator would produce the second derivative with respect to time, which is less likely to be useful.

Transitional Operators

In some cases, an action needs to be triggered when an expression changes from true to false or vice versa. The following operators take a logical expression as an operand, and return a logical expression:

`rising` Has the value `true` when the operand transitions from `false` to `true` in consecutive samples.

`falling` Has the value `false` when the operand transitions from `true` to `false` in consecutive samples.

pmie Examples

The examples presented in this section are task-oriented and use the full power of the **pmie** specification language as described in the section called "Specification Language for **pmie**".

Source code for the **pmie** examples in this chapter, and many more examples, is provided within the *PCP Tutorials and Case Studies*. Example 5.10, "Monitoring CPU Utilization" and Example 5.11, "Monitoring Disk Activity " illustrate monitoring CPU utilization and disk activity.

Example 5.10. Monitoring CPU Utilization

```
// Some Common Performance Monitoring Scenarios
//
// The CPU Group
//
delta = 2 sec;  // more often for demonstration purposes
// common prefixes
//
percpu  = "kernel.percpu";
all     = "kernel.all";
// Unusual usr-sys split when some CPU is more than 20% in usr mode
// and sys mode is at least 1.5 times usr mode
//
cpu_usr_sys =
       some_inst (
           $percpu.cpu.sys > $percpu.cpu.user * 1.5 &&
           $percpu.cpu.user > 0.2
       )
           ->  alarm "Unusual sys time: " "%i ";
// Over all CPUs, syscall_rate > 1000 * no_of_cpus
//
cpu_syscall =
       $all.syscall > 1000 count/sec * hinv.ncpu
```

```
       ->  print "high aggregate syscalls: %v";
// Sustained high syscall rate on a single CPU
//
delta = 30 sec;
percpu_syscall =
       some_inst (
           $percpu.syscall > 2000 count/sec
       )
           -> syslog "Sustained syscalls per second? " "[%i] %v ";
// the 1 minute load average exceeds 5 * number of CPUs on any host
hosts = ":gonzo :moomba";   // change as required
delta = 1 minute;           // no need to evaluate more often than this
high_load =
     some_host (
           $all.load $hosts #'1 minute' > 5 * hinv.ncpu
       )
           -> alarm "High Load Average? " "%h: %v ";
```

Example 5.11. Monitoring Disk Activity

```
// Some Common Performance Monitoring Scenarios
//
// The Disk Group
//
delta = 15 sec;         // often enough for disks?
// common prefixes
//
disk    = "disk";
// Any disk performing more than 40 I/Os per second, sustained over
// at least 30 seconds is probably busy
//
delta = 30 seconds;
disk_busy =
       some_inst (
           $disk.dev.total > 40 count/sec
       )
]      -> shell "Mail -s 'Heavy systained disk traffic' sysadm";
// Try and catch bursts of activity ... more than 60 I/Os per second
// for at least 25% of 8 consecutive 3 second samples
//
delta = 3 sec;
disk_burst =
       some_inst (
           25%_sample (
               $disk.dev.total @0..7 > 60 count/sec
           )
       )
       -> alarm "Disk Burst? " "%i ";
// any SCSI disk controller performing more than 3 Mbytes per
// second is busy
// Note: the obscure 512 is to convert blocks/sec to byte/sec,
//       and pmie handles the rest of the scale conversion
//
some_inst $disk.ctl.blktotal * 512 > 3 Mbyte/sec
```

```
        -> alarm "Busy Disk Controller: " "%i ";
```

Developing and Debugging pmie Rules

Given the `-d` command line option, **pmie** executes in interactive mode, and the user is presented with a menu of options:

```
pmie debugger commands
     f [file-name]      - load expressions from given file or stdin
     l [expr-name]      - list named expression or all expressions
     r [interval]       - run for given or default interval
     S time-spec        - set start time for run
     T time-spec        - set default interval for run command
     v [expr-name]      - print subexpression for %h, %i and %v bindings
     h or ?             - print this menu of commands
     q                  - quit
pmie>
```

If both the `-d` option and a filename are present, the expressions in the given file are loaded before entering interactive mode. Interactive mode is useful for debugging new rules.

Caveats and Notes on pmie

The following sections provide important information for users of **pmie**.

Performance Metrics Wraparound

Performance metrics that are cumulative counters may occasionally overflow their range and wraparound to 0. When this happens, an unknown value (printed as `?`) is returned as the value of the metric for one sample (recall that the value returned is normally a rate). You can have PCP interpolate a value based on expected rate of change by setting the `PCP_COUNTER_WRAP` environment variable.

pmie Sample Intervals

The sample interval (`delta`) should always be long enough, particularly in the case of rates, to ensure that a meaningful value is computed. Interval may vary according to the metric and your needs. A reasonable minimum is in the range of ten seconds or several minutes. Although PCP supports sampling rates up to hundreds of times per second, using small sample intervals creates unnecessary load on the monitored system.

pmie Instance Names

When you specify a metric instance name (*`#identifier`*) in a **pmie** expression, it is compared against the instance name looked up from either a live collector system or an archive as follows:

- If the given instance name and the looked up name are the same, they are considered to match.
- Otherwise, the first two space separated tokens are extracted from the looked up name. If the given instance name is the same as either of these tokens, they are considered a match.

For some metrics, notably the per process (`proc.xxx.xxx`) metrics, the first token in the looked up instance name is impossible to determine at the time you are writing **pmie** expressions. The above policy circumvents this problem.

pmie Error Detection

The parser used in **pmie** is not particularly robust in handling syntax errors. It is suggested that you check any problematic expressions individually in interactive mode:

```
pmie -v -d
pmie> f
expression
Ctrl+D
```

If the expression was parsed, its internal representation is shown:

```
pmie> l
```

The expression is evaluated twice and its value printed:

```
pmie> r 10sec
```

Then quit:

```
pmie> q
```

It is not always possible to detect semantic errors at parse time. This happens when a performance metric descriptor is not available from the named host at this time. A warning is issued, and the expression is put on a wait list. The wait list is checked periodically (about every five minutes) to see if the metric descriptor has become available. If an error is detected at this time, a message is printed to the standard error stream (**stderr**) and the offending expression is set aside.

Creating pmie Rules with pmieconf

The **pmieconf** tool is a command line utility that is designed to aid the specification of **pmie** rules from parameterized versions of the rules. **pmieconf** is used to display and modify variables or parameters controlling the details of the generated **pmie** rules.

pmieconf reads two different forms of supplied input files and produces a localized **pmie** configuration file as its output.

The first input form is a generalized **pmie** rule file such as those found below `${PCP_VAR_DIR}/config/pmieconf`. These files contain the generalized rules which **pmieconf** is able to manipulate. Each of the rules can be enabled or disabled, or the individual variables associated with each rule can be edited.

The second form is an actual **pmie** configuration file (that is, a file which can be interpreted by **pmie**, conforming to the **pmie** syntax described in the section called “Specification Language for **pmie**”). This file is both input to and output from **pmieconf**.

The input version of the file contains any changed variables or rule states from previous invocations of **pmieconf**, and the output version contains both the changes in state (for any subsequent **pmieconf** sessions) and the generated **pmie** syntax. The **pmieconf** state is embedded within a **pmie** comment block at the head of the output file and is not interpreted by **pmie** itself.

pmieconf is an integral part of the **pmie** daemon management process described in the section called “Management of **pmie** Processes”. Procedure 5.1, “Display **pmieconf** Rules” and Procedure 5.2, “Modify

pmieconf Rules and Generate a **pmie** File" introduce the **pmieconf** tool through a series of typical operations.

Procedure 5.1. Display pmieconf Rules

1. Start **pmieconf** interactively (as the superuser).

```
pmieconf -f ${PCP_SYSCONF_DIR}/pmie/config.demo
Updates will be made to ${PCP_SYSCONF_DIR}/pmie/config.demo

pmieconf>
```

2. List the set of available **pmieconf** rules by using the **rules** command.

3. List the set of rule groups using the **groups** command.

4. List only the enabled rules, using the **rules enabled** command.

5. List a single rule:

```
pmieconf> list memory.swap_low
   rule: memory.swap_low  [Low free swap space]
   help: There is only threshold percent swap space remaining - the system
         may soon run out of virtual memory.  Reduce the number and size of
         the running programs or add more swap(1) space before it
completely
         runs out.
         predicate =
           some_host (
               ( 100 * ( swap.free $hosts$ / swap.length $hosts$ ) )
                 < $threshold$
               && swap.length $hosts$ > 0        // ensure swap in use
            )
   vars: enabled = no
         threshold = 10%

pmieconf>
```

6. List one rule variable:

```
pmieconf> list memory.swap_low threshold
   rule: memory.swap_low  [Low free swap space]
         threshold = 10%

pmieconf>
```

Procedure 5.2. Modify pmieconf Rules and Generate a pmie File

1. Lower the threshold for the `memory.swap_low` rule, and also change the **pmie** sample interval affecting just this rule. The `delta` variable is special in that it is not associated with any particular rule; it has been defined as a global **pmieconf** variable. Global variables can be displayed using the **list global** command to **pmieconf**, and can be modified either globally or local to a specific rule.

```
pmieconf> modify memory.swap_low threshold 5

pmieconf> modify memory.swap_low delta "1 sec"
```

```
pmieconf>
```

2. Disable all of the rules except for the `memory.swap_low` rule so that you can see the effects of your change in isolation.

   This produces a relatively simple **pmie** configuration file:

```
pmieconf> disable all

pmieconf> enable memory.swap_low

pmieconf> status
  verbose:  off
  enabled rules:  1 of 35
  pmie configuration file:  ${PCP_SYSCONF_DIR}/pmie/config.demo
  pmie processes (PIDs) using this file:  (none found)

pmieconf> quit
```

   You can also use the **status** command to verify that only one rule is enabled at the end of this step.

3. Run **pmie** with the new configuration file. Use a text editor to view the newly generated **pmie** configuration file (`${PCP_SYSCONF_DIR}/pmie/config.demo`), and then run the command:

```
pmie -T "1.5 sec" -v -l ${HOME}/demo.log ${PCP_SYSCONF_DIR}/pmie/config.demo
memory.swap_low: false

memory.swap_low: false

cat ${HOME}/demo.log
Log for pmie on venus started Mon Jun 21 16:26:06 2012

pmie: PID = 21847, default host = venus

[Mon Jun 21 16:26:07] pmie(21847) Info: evaluator exiting

Log finished Mon Jun 21 16:26:07 2012
```

4. Notice that both of the **pmieconf** files used in the previous step are simple text files, as described in the **pmieconf(5)** man page:

```
file ${PCP_SYSCONF_DIR}/pmie/config.demo
${PCP_SYSCONF_DIR}/pmie/config.demo:  PCP pmie config (V.1)
file ${PCP_VAR_DIR}/config/pmieconf/memory/swap_low
${PCP_VAR_DIR}/config/pmieconf/memory/swap_low:       PCP pmieconf rules (V.1)
```

Management of pmie Processes

The **pmie** process can be run as a daemon as part of the system startup sequence, and can thus be used to perform automated, live performance monitoring of a running system. To do this, run these commands (as superuser):

```
chkconfig pmie on
```

```
${PCP_RC_DIR}/pmie start
```

By default, these enable a single **pmie** process monitoring the local host, with the default set of **pmieconf** rules enabled (for more information about **pmieconf**, see the section called "Creating **pmie** Rules with **pmieconf**"). Procedure 5.3, "Add a New **pmie** Instance to the **pmie** Daemon Management Framework" illustrates how you can use these commands to start any number of **pmie** processes to monitor local or remote machines.

Procedure 5.3. Add a New pmie Instance to the pmie Daemon Management Framework

1. Use a text editor (as superuser) to edit the **pmie**`${PCP_PMIECONTROL_PATH}` and `${PCP_PMIECONTROL_PATH}.d` control files. Notice the default entry, which looks like this:

   ```
   #Host           P?  S?  Log File                                  Arguments
   LOCALHOSTNAME   y   n   PCP_LOG_DIR/pmie/LOCALHOSTNAME/pmie.log   -c config.def
   ```

   This entry is used to enable a local **pmie** process. Add a new entry for a remote host on your local network (for example, `venus`), by using your **pmie** configuration file (see the section called "Creating **pmie** Rules with **pmieconf**"):

   ```
   #Host           P?  S?  Log File                                  Arguments
   venus           n   n   PCP_LOG_DIR/pmie/venus/pmie.log          -c config.dem
   ```

   #### Note

   Without an absolute path, the configuration file (`-c` above) will be resolved using `${PCP_SYSCONF_DIR}/pmie` - if `config.demo` was created in Procedure 5.2, "Modify **pmieconf** Rules and Generate a **pmie** File" it would be used here for host `venus`, otherwise a new configuration file will be generated using the default rules (at `${PCP_SYSCONF_DIR}/pmie/config.demo`).

2. Enable **pmie** daemon management:

   ```
   chkconfig pmie on
   ```

   This simple step allows **pmie** to be started as part of your machine's boot process.

3. Start the two **pmie** daemons. At the end of this step, you should see two new **pmie** processes monitoring the local and remote hosts:

   ```
   ${PCP_RC_DIR}/pmie start
   Performance Co-Pilot starting inference engine(s) ...
   ```

   Wait a few moments while the startup scripts run. The **pmie** start script uses the **pmie_check** script to do most of its work.

   Verify that the **pmie** processes have started:

   ```
   pcp
   Performance Co-Pilot configuration on pluto:

    platform: Linux pluto 3.10.0-0.rc7.64.el7.x86_64 #1 SMP
    hardware: 8 cpus, 2 disks, 23960MB RAM
    timezone: EST-10
   ```

```
pmcd: Version 3.11.3-1, 8 agents
pmda: pmcd proc xfs linux mmv infiniband gluster elasticsearch
pmie: pluto: ${PCP_LOG_DIR}/pmie/pluto/pmie.log
      venus: ${PCP_LOG_DIR}/pmie/venus/pmie.log
```

If a remote host is not up at the time when **pmie** is started, the **pmie** process may exit. **pmie** processes may also exit if the local machine is starved of memory resources. To counter these adverse cases, it can be useful to have a **crontab** entry running. Adding an entry as shown in the section called "Add a **pmie crontab** Entry" ensures that if one of the configured **pmie** processes exits, it is automatically restarted.

Note

Depending on your platform, the **crontab** entry discussed here may already have been installed for you, as part of the package installation process. In this case, the file `/etc/cron.d/pcp-pmie` will exist, and the rest of this section can be skipped.

Add a pmie crontab Entry

To activate the maintenance and housekeeping scripts for a collection of inference engines, execute the following tasks while logged into the local host as the superuser (`root`):

1. Augment the `crontab` file for the `pcp` user. For example:

   ```
   crontab -l -u pcp > ${HOME}/crontab.txt
   ```

2. Edit `${HOME}/crontab.txt`, adding lines similar to those from the sample `${PCP_VAR_DIR}/config/pmie/crontab` file for `pmie_daily` and `pmie_check`; for example:

   ```
   # daily processing of pmie logs
   10     0     *     *     *    ${PCP_BINADM_DIR}/pmie_daily
   # every 30 minutes, check pmie instances are running
   25,55  *     *     *     *    ${PCP_BINADM_DIR}/pmie_check
   ```

3. Make these changes permanent with this command:

   ```
   crontab -u pcp < ${HOME}/crontab.txt
   ```

Global Files and Directories

The following global files and directories influence the behavior of **pmie** and the **pmie** management scripts:

`${PCP_DEMOS_DIR}/pmie/*`	Contains sample **pmie** rules that may be used as a basis for developing local rules.
`${PCP_SYSCONF_DIR}/pmie/config.default`	Is the default **pmie** configuration file that is used when the **pmie** daemon facility is enabled. Generated by **pmieconf** if not manually setup beforehand.
`${PCP_VAR_DIR}/config/pmieconf/*/*`	Contains the **pmieconf** rule definitions (templates) in its subdirectories.
`${PCP_PMIECONTROL_PATH}` and `${PCP_PMIECONTROL_PATH}.d` files	Defines which PCP collector hosts require a daemon **pmie** to be launched on the local host, where the configuration file comes

	from, where the **pmie** log file should be created, and **pmie** startup options.
`${PCP_VAR_DIR}/config/pmlogger/crontab`	Contains default **crontab** entries that may be merged with the **crontab** entries for root to schedule the periodic execution of the **pmie_check** script, for verifying that **pmie** instances are running. Only for platforms where a default **crontab** is not automatically installed during the initial PCP package installation.
`${PCP_LOG_DIR}/pmie/*`	Contains the **pmie** log files for the host. These files are created by the default behavior of the `${PCP_RC_DIR}/pmie` startup scripts.

pmie Instances and Their Progress

The PMCD PMDA exports information about executing **pmie** instances and their progress in terms of rule evaluations and action execution rates.

pmie_check	This command is similar to the **pmlogger** support script, **pmlogger_check**.
`${PCP_RC_DIR}/pmie`	This start script supports the starting and stopping of multiple **pmie** instances that are monitoring one or more hosts.
`${PCP_TMP_DIR}/pmie`	The statistics that **pmie** gathers are maintained in binary data structure files. These files are located in this directory.
`pmcd.pmie` metrics	If **pmie** is running on a system with a PCP collector deployment, the PMCD PMDA exports these metrics via the `pmcd.pmie` group of metrics.

Chapter 6. Archive Logging

Table of Contents

Performance monitoring and management in complex systems demands the ability to accurately capture performance characteristics for subsequent review, analysis, and comparison. Performance Co-Pilot (PCP) provides extensive support for the creation and management of archive logs that capture a user-specified profile of performance information to support retrospective performance analysis.

The following major sections are included in this chapter:

- the section called “Introduction to Archive Logging”, presents the concepts and issues involved with creating and using archive logs.
- the section called “Using Archive Logs with Performance Tools”, describes the interaction of the PCP tools with archive logs.
- the section called “Cookbook for Archive Logging”, shows some shortcuts for setting up useful PCP archive logs.
- the section called “Other Archive Logging Features and Services”, provides information about other archive logging features and sevices.
- the section called “Archive Logging Troubleshooting”, presents helpful directions if your archive logging implementation is not functioning correctly.

Introduction to Archive Logging

Within the PCP, the **pmlogger** utility may be configured to collect archives of performance metrics. The archive creation process is simple and very flexible, incorporating the following features:

- Archive log creation at either a PCP collector (typically a server) or a PCP monitor system (typically a workstation), or at some designated PCP archive logger host.
- Concurrent independent logging, both local and remote. The performance analyst can activate a private **pmlogger** instance to collect only the metrics of interest for the problem at hand, independent of other logging on the workstation or remote host.
- Independent determination of logging frequency for individual metrics or metric instances. For example, you could log the “5 minute” load average every half hour, the write I/O rate on the DBMS log spindle every 10 seconds, and aggregate I/O rates on the other disks every minute.
- Dynamic adjustment of what is to be logged, and how frequently, via **pmlc**. This feature may be used to disable logging or to increase the sample interval during periods of low activity or chronic high activity. A local **pmlc** may interrogate and control a remote **pmlogger**, subject to the access control restrictions implemented by **pmlogger**.
- Self-contained logs that include all system configuration and metadata required to interpret the values in the log. These logs can be kept for analysis at a much later time, potentially after the hardware or software has been reconfigured and the logs have been stored as discrete, autonomous files for remote analysis. The logs are endian-neutral and platform independent - there is no requirement that the monitor host machine used for analysis be similar to the collector machine in any way, nor do they have to have the same versions of PCP. PCP archives created over 15 years ago can still be replayed with the current versions of PCP!
- `cron`-based scripts to expedite the operational management, for example, log rotation, consolidation, and culling. Another helper tool, **pmlogconf** can be used to generate suitable logging configurations for a variety of situations.
- Archive folios as a convenient aggregation of multiple archive logs. Archive folios may be created with the **mkaf** utility and processed with the **pmafm** tool.

Archive Logs and the PMAPI

Critical to the success of the PCP archive logging scheme is the fact that the library routines providing access to real-time feeds of performance metrics also provide access to the archive logs.

Live feeds (or real-time) sources of performance metrics and archives are literally interchangeable, with a single Performance Metrics Application Programming Interface (PMAPI) that preserves the same semantics for both styles of metric source. In this way, applications and tools developed against the PMAPI can automatically process either live or historical performance data.

Retrospective Analysis Using Archive Logs

One of the most important applications of archive logging services provided by PCP is in the area of retrospective analysis. In many cases, understanding today's performance problems can be assisted by side-by-side comparisons with yesterday's performance. With routine creation of performance archive logs, you can concurrently replay pictures of system performance for two or more periods in the past.

Archive logs are also an invaluable source of intelligence when trying to diagnose what went wrong, as in a performance post-mortem. Because the PCP archive logs are entirely self-contained, this analysis can be performed off-site if necessary.

Each archive log contains metric values from only one host. However, many PCP tools can simultaneously visualize values from multiple archives collected from different hosts.

The archives can be replayed using the inference engine (**pmie** is an application that uses the PMAPI). This allows you to automate the regular, first-level analysis of system performance.

Such analysis can be performed by constructing suitable expressions to capture the essence of common resource saturation problems, then periodically creating an archive and playing it against the expressions. For example, you may wish to create a daily performance audit (perhaps run by the **cron** command) to detect performance regressions.

For more about **pmie**, see Chapter 5, *Performance Metrics Inference Engine*.

Using Archive Logs for Capacity Planning

By collecting performance archives with relatively long sampling periods, or by reducing the daily archives to produce summary logs, the capacity planner can collect the base data required for forward projections, and can estimate resource demands and explore “what if” scenarios by replaying data using visualization tools and the inference engine.

Using Archive Logs with Performance Tools

Most PCP tools default to real-time display of current values for performance metrics from PCP collector host(s). However, most PCP tools also have the capability to display values for performance metrics retrieved from PCP archive log(s). The following sections describe plans, steps, and general issues involving archive logs and the PCP tools.

Coordination between pmlogger and PCP tools

Most commonly, a PCP tool would be invoked with the `-a` option to process sets of archive logs some time after **pmlogger** had finished creating the archive. However, a tool such as **pmchart** that uses a Time Control dialog (see the section called “Time Duration and Control”) stops when the end of a set of archives is reached, but could resume if more data is written to the PCP archive log.

Note

pmlogger uses buffered I/O to write the archive log so that the end of the archive may be aligned with an I/O buffer boundary, rather than with a logical archive log record. If such an archive was read by a PCP tool, it would appear truncated and might confuse the tool. These problems may be avoided by sending **pmlogger** a `SIGUSR1` signal, or by using the **flush** command of **pmlc** to force **pmlogger** to flush its output buffers.

Administering PCP Archive Logs Using cron Scripts

Many operating systems support the `cron` process scheduling system.

PCP supplies shell scripts to use the `cron` functionality to help manage your archive logs. The following scripts are supplied:

Script	Description
pmlogger_daily(1)	Performs a daily housecleaning of archive logs and notices.
pmlogger_merge(1)	Merges archive logs and is called by pmlogger_daily.
pmlogger_check(1)	Checks to see that all desired **pmlogger** processes are running on your system, and invokes any that are missing for any reason.
pmlogconf(1)	Generates suitable **pmlogger** configuration files based on a pre-defined set of templates. It can probe the state of the system under observation to make informed decisions about which metrics to record. This is an extensible facility, allowing software upgrades and new PMDA installations to add to the existing set of templates.
pmsnap(1)	Generates graphic image snapshots of **pmchart** performance charts at regular intervals.

The configuration files used by these scripts can be edited to suit your particular needs, and are generally controlled by the ${PCP_PMLOGGERCONTROL_PATH} and ${PCP_PMLOGGERCONTROL_PATH}.d files (pmsnap has an additional control file, ${PCP_PMSNAPCONTROL_PATH}). Complete information on these scripts is available in the **pmlogger_daily(1)** and **pmsnap(1)** man pages.

Archive Log File Management

PCP archive log files can occupy a great deal of disk space, and management of archive logs can be a large task in itself. The following sections provide information to assist you in PCP archive log file management.

Basename Conventions

When a PCP archive is created by **pmlogger**, an archive basename must be specified and several physical files are created, as shown in Table 6.1, “Filenames for PCP Archive Log Components (archive.*)”.

Table 6.1. Filenames for PCP Archive Log Components (archive.*)

Filename	Contents
archive.*index*	Temporal index for rapid access to archive contents.
archive.*meta*	Metadata descriptions for performance metrics and instance domains appearing in the archive.
archive.N	Volumes of performance metrics values, for N = 0,1,2,...

Log Volumes

A single PCP archive may be partitioned into a number of volumes. These volumes may expedite management of the archive; however, the metadata file and at least one volume must be present before a PCP tool can process the archive.

You can control the size of an archive log volume by using the -v command line option to **pmlogger**. This option specifies how large a volume should become before **pmlogger** starts a new volume. Archive

log volumes retain the same base filename as other files in the archive log, and are differentiated by a numeric suffix that is incremented with each volume change. For example, you might have a log volume sequence that looks like this:

```
netserver-log.0
netserver-log.1
netserver-log.2
```

You can also cause an existing log to be closed and a new one to be opened by sending a `SIGHUP` signal to **pmlogger**, or by using the **pmlc** command to change the **pmlogger** instructions dynamically, without interrupting **pmlogger** operation. Complete information on log volumes is found in the **pmlogger(1)** man page.

Basenames for Managed Archive Log Files

The PCP archive management tools support a consistent scheme for selecting the basenames for the files in a collection of archives and for mapping these files to a suitable directory hierarchy.

Once configured, the PCP tools that manage archive logs employ a consistent scheme for selecting the basename for an archive each time **pmlogger** is launched, namely the current date and time in the format YYYYMMDD.HH.MM. Typically, at the end of each day, all archives for a particular host on that day would be merged to produce a single archive with a basename constructed from the date, namely YYYYMMDD. The `pmlogger_daily` script performs this action and a number of other routine housekeeping chores.

Directory Organization for Archive Log Files

If you are using a deployment of PCP tools and daemons to collect metrics from a variety of hosts and storing them all at a central location, you should develop an organized strategy for storing and naming your log files.

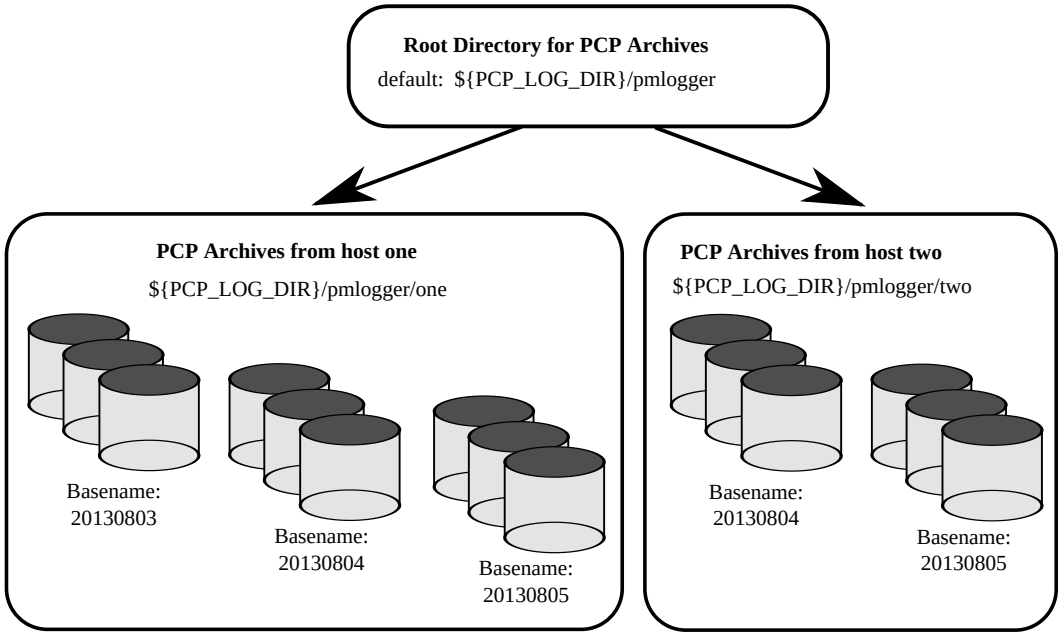
Note

There are many possible configurations of **pmlogger**, as described in the section called "PCP Archive Logger Deployment". The directory organization described in this section is recommended for any system on which **pmlogger** is configured for permanent execution (as opposed to short-term executions, for example, as launched from **pmchart** to record some performance data of current interest).

Typically, the filesystem structure can be used to reflect the number of hosts for which a **pmlogger** instance is expected to be running locally, obviating the need for lengthy and cumbersome filenames. It makes considerable sense to place all logs for a particular host in a separate directory named after that host. Because each instance of **pmlogger** can only log metrics fetched from a single host, this also simplifies some of the archive log management and administration tasks.

For example, consider the filesystem and naming structure shown in Figure 6.1, "Archive Log Directory Structure".

Figure 6.1. Archive Log Directory Structure



The specification of where to place the archive log files for particular **pmlogger** instances is encoded in the `${PCP_PMLOGGERCONTROL_PATH}` and `${PCP_PMLOGGERCONTROL_PATH}.d` configuration files, and these files should be customized on each host running an instance of **pmlogger**.

If many archives are being created, and the associated PCP collector systems form peer classes based upon service type (Web servers, DBMS servers, NFS servers, and so on), then it may be appropriate to introduce another layer into the directory structure, or use symbolic links to group together hosts providing similar service types.

Configuration of pmlogger

The configuration files used by **pmlogger** describe which metrics are to be logged. Groups of metrics may be logged at different intervals to other groups of metrics. Two states, mandatory and advisory, also apply to each group of metrics, defining whether metrics definitely should be logged or not logged, or whether a later advisory definition may change that state.

The mandatory state takes precedence if it is `on` or `off`, causing any subsequent request for a change in advisory state to have no effect. If the mandatory state is `maybe`, then the advisory state determines if logging is enabled or not.

The mandatory states are `on`, `off`, and `maybe`. The advisory states, which only affect metrics that are mandatory `maybe`, are `on` and `off`. Therefore, a metric that is mandatory `maybe` in one definition and advisory `on` in another definition would be logged at the advisory interval. Metrics that are not specified in the **pmlogger** configuration file are mandatory `maybe` and advisory `off` by default and are not logged.

A complete description of the **pmlogger** configuration format can be found on the **pmlogger(1)** man page.

PCP Archive Contents

Once a PCP archive log has been created, the **pmdumplog** utility may be used to display various information about the contents of the archive. For example, start with the following command:

```
pmdumplog -l ${PCP_LOG_DIR}/pmlogger/www.sgi.com/19960731
```

It might produce the following output:

```
Log Label (Log Format Version 1)
Performance metrics from host www.sgi.com
     commencing Wed Jul 31 00:16:34.941 1996
     ending     Thu Aug  1 00:18:01.468 1996
```

The simplest way to discover what performance metrics are contained within a set of archives is to use `pminfo` as shown in Example 6.1, “Using `pminfo` to Obtain Archive Information”:

Example 6.1. Using `pminfo` to Obtain Archive Information

```
pminfo -a ${PCP_LOG_DIR}/pmlogger/www.sgi.com/19960731 network.mbuf
network.mbuf.alloc
network.mbuf.typealloc
network.mbuf.clustalloc
network.mbuf.clustfree
network.mbuf.failed
network.mbuf.waited
network.mbuf.drained
```

Cookbook for Archive Logging

The following sections present a checklist of tasks that may be performed to enable PCP archive logging with minimal effort. For a complete explanation, refer to the other sections in this chapter and the man pages for **pmlogger** and related tools.

Primary Logger

Assume you wish to activate primary archive logging on the PCP collector host `pluto`. Execute the following while logged into `pluto` as the superuser (`root`).

1. Start **pmcd** and **pmlogger**:

```
chkconfig pmcd on
chkconfig pmlogger on
${PCP_RC_DIR}/pmcd start
Starting pmcd ...
${PCP_RC_DIR}/pmlogger start
Starting pmlogger ...
```

2. Verify that the primary **pmlogger** instance is running:

```
pcp
Performance Co-Pilot configuration on pluto:

 platform: Linux pluto 3.10.0-0.rc7.64.el7.x86_64 #1 SMP
 hardware: 8 cpus, 2 disks, 23960MB RAM
 timezone: EST-10
     pmcd: Version 4.0.0-1, 8 agents
     pmda: pmcd proc xfs linux mmv infiniband gluster elasticsearch
```

```
    pmlogger: primary logger: pluto/20170815.10.00
    pmie: pluto: ${PCP_LOG_DIR}/pmie/pluto/pmie.log
          venus: ${PCP_LOG_DIR}/pmie/venus/pmie.log
```

3. Verify that the archive files are being created in the expected place:

```
ls ${PCP_LOG_DIR}/pmlogger/pluto
20170815.10.00.0
20170815.10.00.index
20170815.10.00.meta
Latest
pmlogger.log
```

4. Verify that no errors are being logged, and the rate of expected growth of the archives:

```
cat ${PCP_LOG_DIR}/pmlogger/pluto/pmlogger.log
Log for pmlogger on pluto started Thu Aug 15 10:00:11 2017

Config parsed
Starting primary logger for host "pluto"
Archive basename: 20170815.00.10

Group [26 metrics] {
 hinv.map.lvname
 ...
 hinv.ncpu
} logged once: 1912 bytes

Group [11 metrics] {
 kernel.all.cpu.user
 ...
 kernel.all.load
} logged every 60 sec: 372 bytes or 0.51 Mbytes/day

...
```

Other Logger Configurations

Assume you wish to create archive logs on the local host for performance metrics collected from the remote host `venus`. Execute all of the following tasks while logged into the local host as the superuser (`root`).

Procedure 6.1. Creating Archive Logs

1. Create a suitable **pmlogger** configuration file. There are several options:

   - Run the **pmlogconf(1)** utility to generate a configuration file, and (optionally) interactively customize it further to suit local needs.

     ```
     ${PCP_BINADM_DIR}/pmlogconf ${PCP_SYSCONF_DIR}/pmlogger/config.venus
     Creating config file "${PCP_SYSCONF_DIR}/pmlogger/config.venus" using default

     ${PCP_BINADM_DIR}/pmlogconf ${PCP_SYSCONF_DIR}/pmlogger/config.venus

     Group: utilization per CPU
     ```

```
Log this group? [n] y
Logging interval? [default]

Group: utilization (usr, sys, idle, ...) over all CPUs
Log this group? [y] y
Logging interval? [default]

Group: per spindle disk activity
Log this group? [n] y

...
```

- Do nothing - a default configuration will be created in the following step, using **pmlogconf(1)** probing and automatic file generation based on the metrics available at the remote host. The `${PCP_RC_DIR}/pmlogger` start script handles this.

- Manually - create a configuration file with a text editor, or arrange to have one put in place by configuration management tools like Puppet [https://puppetlabs.com/] or Chef [http://www.opscode.com/chef/].

2. Edit `${PCP_PMLOGGERCONTROL_PATH}`, or one of the `${PCP_PMLOGGERCONTROL_PATH}.d` files. Using the line for `remote` as a template, add the following line:

   venus n n PCP_LOG_DIR/pmlogger/venus -r -T24h10m -c config.venus

3. Start **pmlogger**:

   ```
   ${PCP_BINADM_DIR}/pmlogger_check
   Restarting pmlogger for host "venus" ..... done
   ```

4. Verify that the **pmlogger** instance is running:

   ```
   pcp
   Performance Co-Pilot configuration on pluto:

    platform: Linux pluto 3.10.0-0.rc7.64.el7.x86_64 #1 SMP
    hardware: 8 cpus, 2 disks, 23960MB RAM
    timezone: EST-10
        pmcd: Version 3.8.3-1, 8 agents
        pmda: pmcd proc linux xfs mmv infiniband gluster elasticsearch
        pmlogger: primary logger: pluto/20170815.10.00
              venus.redhat.com: venus/20170815.11.15
   pmlc
   pmlc> show loggers
   The following pmloggers are running on pluto:
           primary (19144) 5141
   pmlc> connect 5141
   pmlc> status
   pmlogger [5141] on host pluto is logging metrics from host venus
   log started      Thu Aug 15 11:15:39 2017 (times in local time)
   last log entry   Thu Aug 15 11:47:39 2017
   current time     Thu Aug 15 11:48:13 2017
   log volume       0
   log size         146160
   ```

To create archive logs on the local host for performance metrics collected from multiple remote hosts, repeat the steps in Procedure 6.1, “Creating Archive Logs” for each remote host (each with a new `control` file entry).

Archive Log Administration

Assume the local host has been set up to create archive logs of performance metrics collected from one or more hosts (which may be either the local host or a remote host).

Note

Depending on your platform, the **crontab** entry discussed here may already have been installed for you, as part of the package installation process. In this case, the file `/etc/cron.d/pcp-pmlogger` will exist, and the rest of this section can be skipped.

To activate the maintenance and housekeeping scripts for a collection of archive logs, execute the following tasks while logged into the local host as the superuser (`root`):

1. Augment the `crontab` file for the `pcp` user. For example:

   ```
   crontab -l -u pcp > ${HOME}/crontab.txt
   ```

2. Edit `${HOME}/crontab.txt`, adding lines similar to those from the sample `${PCP_VAR_DIR}/config/pmlogger/crontab` file for `pmlogger_daily` and `pmlogger_check`; for example:

   ```
   # daily processing of archive logs
   10     0     *     *     *    ${PCP_BINADM_DIR}/pmlogger_daily
   # every 30 minutes, check pmlogger instances are running
   25,55  *     *     *     *    ${PCP_BINADM_DIR}/pmlogger_check
   ```

3. Make these changes permanent with this command:

   ```
   crontab -u pcp < ${HOME}/crontab.txt
   ```

Other Archive Logging Features and Services

Other archive logging features and services include PCP archive folios, manipulating archive logs, primary logger, and using **pmlc**.

PCP Archive Folios

A collection of one or more sets of PCP archive logs may be combined with a control file to produce a PCP archive folio. Archive folios are created using either `mkaf` or the interactive record mode services of various PCP monitor tools (e.g. **pmchart** and **pmrep**).

The automated archive log management services also create an archive folio named `Latest` for each managed **pmlogger** instance, to provide a symbolic name to the most recent archive log. With reference to Figure 6.1, “Archive Log Directory Structure”, this would mean the creation of the folios `${PCP_LOG_DIR}/pmlogger/one/Latest` and `${PCP_LOG_DIR}/pmlogger/two/Latest`.

The **pmafm** utility is completely described in the **pmafm(1)** man page, and provides the interactive commands (single commands may also be executed from the command line) for the following services:

- Checking the integrity of the archives in the folio.
- Displaying information about the component archives.
- Executing PCP tools with their source of performance metrics assigned concurrently to all of the component archives (where the tool supports this), or serially executing the PCP tool once per component archive.
- If the folio was created by a single PCP monitoring tool, replaying all of the archives in the folio with that monitoring tool.
- Restricting the processing to particular archives, or the archives associated with particular hosts.

Manipulating Archive Logs with pmlogextract

The `pmlogextract` tool takes a number of PCP archive logs from a single host and performs the following tasks:

- Merges the archives into a single log, while maintaining the correct time stamps for all values.
- Extracts all metric values within a temporal window that could encompass several archive logs.
- Extracts only a configurable subset of metrics from the archive logs.

See the **pmlogextract(1)** man page for full information on this command.

Summarizing Archive Logs with pmlogsummary

The `pmlogsummary` tool provides statistical summaries of archives, or specific metrics within archives, or specific time windows of interest in a set of archives. These summaries include various averages, minima, maxima, sample counts, histogram bins, and so on.

As an example, for Linux host `pluto`, report on its use of anonymous huge pages - average use, maximum, time at which maximum occured, total number of samples in the set of archives, and the units used for the values - as shown in Example 6.2, “Using `pmlogsummary` to Summarize Archive Information”:

Example 6.2. Using `pmlogsummary` to Summarize Archive Information

```
pmlogsummary -MIly ${PCP_LOG_DIR}/pmlogger/pluto/20170815 mem.util.anonhugepages
Performance metrics from host pluto
  commencing Thu Aug 15 00:10:12.318 2017
  ending     Fri Aug 16 00:10:12.299 2017

mem.util.anonhugepages  7987742.326 8116224.000 15:02:12.300 1437 Kbyte

pminfo -t mem.util.anonhugepages
mem.util.anonhugepages [amount of memory in anonymous huge pages]
```

See the **pmlogsummary(1)** man page for detailed information about this commands many options.

Primary Logger

On each system for which PMCD is active (each PCP collector system), there is an option to have a distinguished instance of the archive logger **pmlogger** (the “primary” logger) launched each time PMCD is started. This may be used to ensure the creation of minimalist archive logs required for ongoing system

management and capacity planning in the event of failure of a system where a remote **pmlogger** may be running, or because the preferred archive logger deployment is to activate **pmlogger** on each PCP collector system.

Run the following command as superuser on each PCP collector system where you want to activate the primary **pmlogger**:

```
chkconfig pmlogger on
```

The primary logger launches the next time the **${PCP_RC_DIR}/pmlogger start** script runs. If you wish this to happen immediately, follow up with this command:

```
${PCP_BINADM_DIR}/pmlogger_check -V
```

When it is started in this fashion, the `${PCP_PMLOGGERCONTROL_PATH}` file (or one of the `${PCP_PMLOGGERCONTROL_PATH}.d` files) must use the second field of one configuration line to designate the primary logger, and usually will also use the **pmlogger** configuration file `${PCP_SYSCONF_DIR}/pmlogger/config.default` (although the latter is not mandatory).

Using pmlc

You may tailor **pmlogger** dynamically with the **pmlc** command (if it is configured to allow access to this functionality). Normally, the **pmlogger** configuration is read at startup. If you choose to modify the `config` file to change the parameters under which **pmlogger** operates, you must stop and restart the program for your changes to have effect. Alternatively, you may change parameters whenever required by using the **pmlc** interface.

To run the **pmlc** tool, enter:

```
pmlc
```

By default, **pmlc** acts on the primary instance of **pmlogger** on the current host. See the **pmlc(1)** man page for a description of command line options. When it is invoked, **pmlc** presents you with a prompt:

```
pmlc>
```

You may obtain a listing of the available commands by entering a question mark (?) and pressing **Enter**. You see output similar to that in Example 6.3, “Listing Available Commands ”:

Example 6.3. Listing Available Commands

```
show loggers [@<host>]           display <pid>s of running pmloggers
connect _logger_id [@<host>]     connect to designated pmlogger
status                           information about connected pmlogger
query metric-list                show logging state of metrics
new volume                       start a new log volume
flush                            flush the log buffers to disk
log { mandatory | advisory } on <interval> _metric-list
log { mandatory | advisory } off _metric-list
log mandatory maybe _metric-list
timezone local|logger|'<timezone>' change reporting timezone
help                               print this help message
quit                               exit from pmlc
_logger_id   is  primary | <pid> | port <n>
_metric-list is  _metric-spec | { _metric-spec ... }
```

```
     _metric-spec is  <metric-name> | <metric-name> [ <instance> ... ]
```

Here is an example:

```
pmlc
pmlc> show loggers @babylon
The following pmloggers are running on babylon:
       primary (1892)
pmlc> connect 1892 @babylon
pmlc> log advisory on 2 secs disk.dev.read
pmlc> query disk.dev
disk.dev.read
       adv  on  nl       5 min  [131073 or “disk1”]
       adv  on  nl       5 min  [131074 or “disk2”]
pmlc> quit
```

Note

Any changes to the set of logged metrics made via **pmlc** are not saved, and are lost the next time **pmlogger** is started with the same configuration file. Permanent changes are made by modifying the **pmlogger** configuration file(s).

Refer to the **pmlc(1)** and **pmlogger(1)** man pages for complete details.

Archive Logging Troubleshooting

The following issues concern the creation and use of logs using **pmlogger**.

pmlogger Cannot Write Log

Symptom: The **pmlogger** utility does not start, and you see this message:

```
__pmLogNewFile: “foo.index” already exists, not over-written
```

Cause: Archive logs are considered sufficiently precious that **pmlogger** does not empty or overwrite an existing set of archive log files. The log named `foo` actually consists of the physical file `foo.index`, `foo.meta`, and at least one file `foo.N`, where `N` is in the range 0, 1, 2, 3, and so on.

A message similar to the one above is produced when a new **pmlogger** instance encounters one of these files already in existence.

Resolution: Move the existing archive aside, or if you are sure, remove all of the parts of the archive log. For example, use the following command:

```
rm -f foo.*
```

Then rerun **pmlogger**.

Cannot Find Log

Symptom: The `pmdumplog` utility, or any tool that can read an archive log, displays this message:

```
Cannot open archive mylog: No such file or directory
```

Cause: An archive consists of at least three physical files. If the base name for the archive is `mylog`, then the archive actually consists of the physical files `mylog.index`, `mylog.meta`, and at least one file `mylog.N`, where `N` is in the range 0, 1, 2, 3, and so on.

The above message is produced if one or more of the files is missing.

Resolution: Use this command to check which files the utility is trying to open:

```
ls mylog.*
```

Turn on the internal debug flag `DBG_TRACE_LOG` (`-D` 128) to see which files are being inspected by the `pmOpenLog` routine as shown in the following example:

```
pmdumplog -D 128 -l mylog
```

Locate the missing files and move them all to the same directory, or remove all of the files that are part of the archive, and recreate the archive log.

Primary pmlogger Cannot Start

Symptom: The primary **pmlogger** cannot be started. A message like the following appears:

```
pmlogger: there is already a primary pmlogger running
```

Cause: There is either a primary **pmlogger** already running, or the previous primary **pmlogger** was terminated unexpectedly before it could perform its cleanup operations.

Resolution: If there is already a primary **pmlogger** running and you wish to replace it with a new **pmlogger**, use the `show` command in **pmlc** to determine the process ID of the primary **pmlogger**. The process ID of the primary **pmlogger** appears in parentheses after the word “primary.” Send a `SIGINT` signal to the process to shut it down (use either the **kill** command if the platform supports it, or the **pmsignal** command). If the process does not exist, proceed to the manual cleanup described in the paragraph below. If the process did exist, it should now be possible to start the new **pmlogger**.

If **pmlc**'s **show** command displays a process ID for a process that does not exist, a **pmlogger** process was terminated before it could clean up. If it was the primary **pmlogger**, the corresponding control files must be removed before one can start a new primary **pmlogger**. It is a good idea to clean up any spurious control files even if they are not for the primary **pmlogger**.

The control files are kept in `${PCP_TMP_DIR}/pmlogger`. A control file with the process ID of the **pmlogger** as its name is created when the **pmlogger** is started. In addition, the primary **pmlogger** creates a symbolic link named `primary` to its control file.

For the primary **pmlogger**, remove both the symbolic link and the file (corresponding to its process ID) to which the link points. For other **pmlogger**s, remove just the process ID file. Do not remove any other files in the directory. If the control file for an active **pmlogger** is removed, **pmlc** is not able to contact it.

Identifying an Active pmlogger Process

Symptom: You have a PCP archive log that is demonstrably growing, but do not know the identify of the associated **pmlogger** process.

Cause: The PID is not obvious from the log, or the archive name may not be obvious from the output of the **ps** command.

Resolution: If the archive basename is `foo`, run the following commands:

```
pmdumplog -l foo
Log Label (Log Format Version 1)
Performance metrics from host gonzo
     commencing Wed Aug  7 00:10:09.214 1996
     ending     Wed Aug  7 16:10:09.155 1996

pminfo -a foo -f pmcd.pmlogger
pmcd.pmlogger.host
     inst [10728 or "10728"] value "gonzo"
pmcd.pmlogger.port
     inst [10728 or "10728"] value 4331
pmcd.pmlogger.archive
     inst [10728 or "10728"] value "/usr/var/adm/pcplog/gonzo/fo
```

All of the information describing the creator of the archive is revealed and, in particular, the instance identifier for the PMCD metrics (`10728` in the example above) is the PID of the **pmlogger** instance, which may be used to control the process via **pmlc**.

Illegal Label Record

Symptom: PCP tools report:

```
Illegal label record at start of PCP archive log file.
```

Cause: The label record at the start of each of the physical archive log files has become either corrupted or one is out of sync with the others.

Resolution: If you believe the log may have been corrupted, this can be verified using **pmlogcheck**. If corruption is limited to just the label record at the start, the **pmloglabel** can be used to force the labels back in sync with each other, with known-good values that you supply.

Refer to the **pmlogcheck(1)** and **pmloglabel(1)** man pages.

Empty Archive Log Files or pmlogger Exits Immediately

Symptom: Archive log files are zero size, requested metrics are not being logged, or **pmlogger** exits immediately with no error messages.

Cause: Either **pmlogger** encountered errors in the configuration file, has not flushed its output buffers yet, or some (or all) metrics specified in the **pmlogger** configuration file have had their state changed to advisory `off` or mandatory `off` via **pmlc**. It is also possible that the logging interval specified in the

pmlogger configuration file for some or all of the metrics is longer than the period of time you have been waiting since **pmlogger** started.

Resolution: If **pmlogger** exits immediately with no error messages, check the `pmlogger.log` file in the directory **pmlogger** was started in for any error messages. If **pmlogger** has not yet flushed its buffers, enter one of the following commands (depending on platform support):

```
killall -SIGUSR1 pmlogger
${PCP_BINADM_DIR}/pmsignal -a -s USR1 pmlogger
```

Otherwise, use the `status` command for **pmlc** to interrogate the internal **pmlogger** state of specific metrics.

Chapter 7. Performance Co-Pilot Deployment Strategies

Table of Contents

Performance Co-Pilot (PCP) is a coordinated suite of tools and utilities allowing you to monitor performance and make automated judgments and initiate actions based on those judgments. PCP is designed to be fully configurable for custom implementation and deployed to meet specific needs in a variety of operational environments.

Because each enterprise and site is different and PCP represents a new way of managing performance information, some discussion of deployment strategies is useful.

The most common use of performance monitoring utilities is a scenario where the PCP tools are executed on a workstation (the PCP monitoring system), while the interesting performance data is collected on remote systems (PCP collector systems) by a number of processes, specifically the Performance Metrics Collection Daemon (PMCD) and the associated Performance Metrics Domain Agents (PMDAs). These processes can execute on both the monitoring system and one or more collector systems, or only on collector systems. However, collector systems are the real objects of performance investigations.

The material in this chapter covers the following areas:

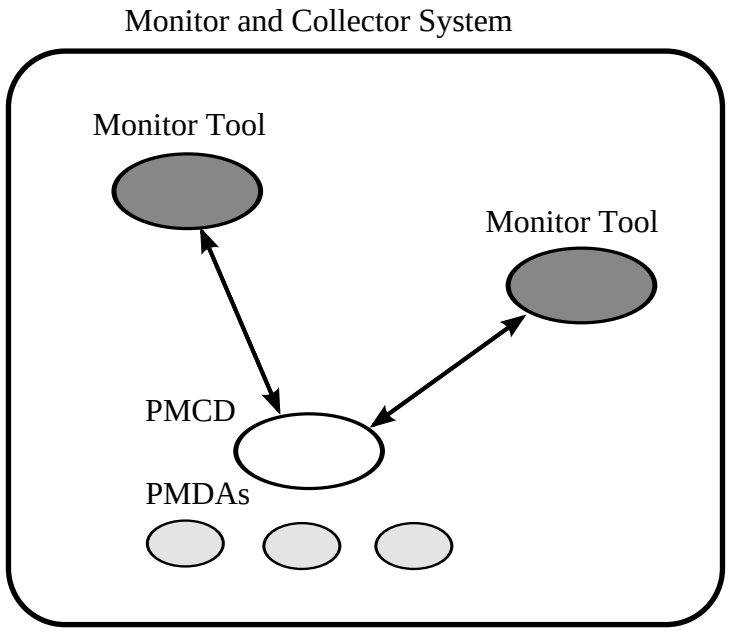
- the section called “Basic Deployment”, presents the spectrum of deployment architectures at the highest level.
- the section called “PCP Collector Deployment”, describes alternative deployments for PMCD and the PMDAs.
- the section called “PCP Archive Logger Deployment”, covers alternative deployments for the **pmlogger** tool.
- the section called “PCP Inference Engine Deployment”, presents the options that are available for deploying the **pmie** tool.

The options shown in this chapter are merely suggestions. They are not comprehensive, and are intended to demonstrate some possible ways of deploying the PCP tools for specific network topologies and purposes. You are encouraged to use them as the basis for planning your own deployment, consistent with your needs.

Basic Deployment

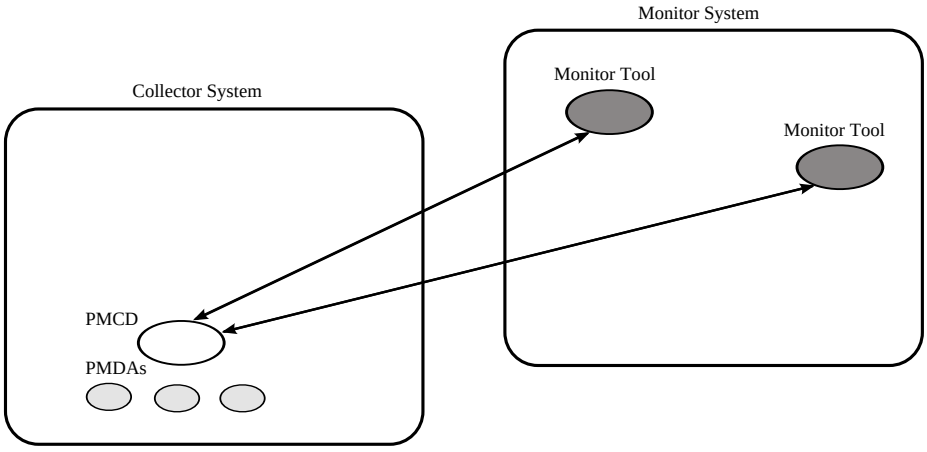
In the simplest PCP deployment, one system is configured as both a collector and a monitor, as shown in Figure 7.1, “PCP Deployment for a Single System”. Because some of the PCP monitor tools make extensive use of visualization, this suggests the monitor system should be configured with a graphical display.

Figure 7.1. PCP Deployment for a Single System



However, most PCP deployments involve at least two systems. For example, the setup shown in Figure 7.2, “Basic PCP Deployment for Two Systems” would be representative of many common scenarios.

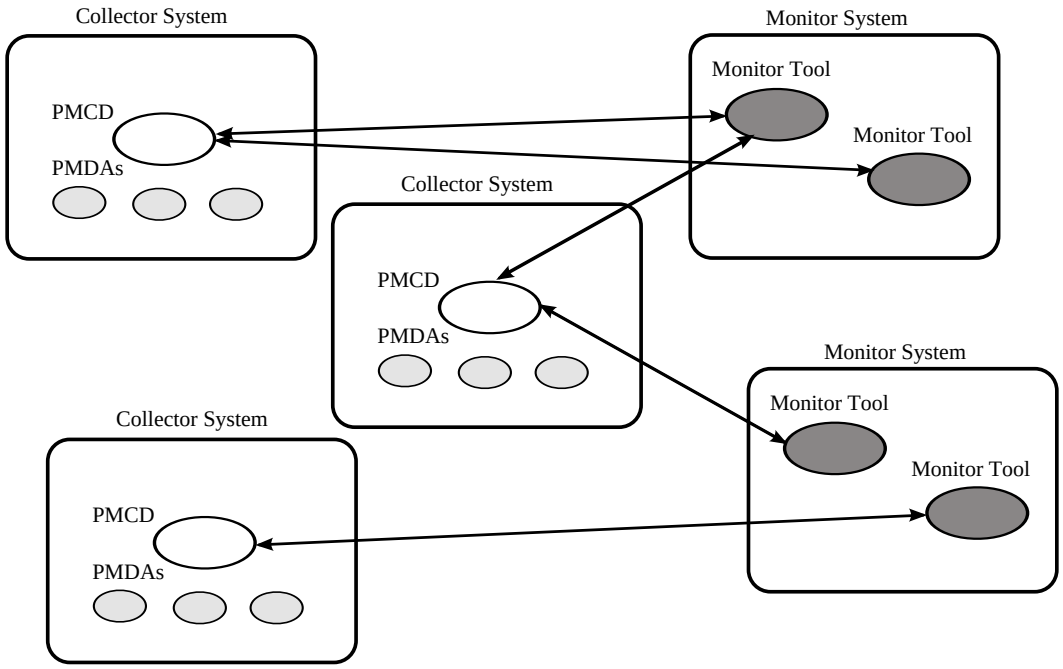
Figure 7.2. Basic PCP Deployment for Two Systems



But the most common site configuration would include a mixture of systems configured as PCP collectors, as PCP monitors, and as both PCP monitors and collectors, as shown in Figure 7.3, “General PCP Deployment for Multiple Systems ”.

With one or more PCP collector systems and one or more PCP monitor systems, there are a number of decisions that need to be made regarding the deployment of PCP services across multiple hosts. For example, in Figure 7.3, “General PCP Deployment for Multiple Systems ” there are several ways in which both the inference engine (**pmie**) and the PCP archive logger (**pmlogger**) could be deployed. These options are discussed in the following sections of this chapter.

Figure 7.3. General PCP Deployment for Multiple Systems



PCP Collector Deployment

Each PCP collector system must have an active `pmcd` and, typically, a number of PMDAs installed.

Principal Server Deployment

The first hosts selected as PCP collector systems are likely to provide some class of service deemed to be critical to the information processing activities of the enterprise. These hosts include:

- Database servers
- Web servers for an Internet or Intranet presence
- NFS or other central storage server
- A video server
- A supercomputer
- An infrastructure service provider, for example, print, DNS, LDAP, gateway, firewall, router, or mail services
- Any system running a mission-critical application

Your objective may be to improve quality of service on a system functioning as a server for many clients. You wish to identify and repair critical performance bottlenecks and deficiencies in order to maintain maximum performance for clients of the server.

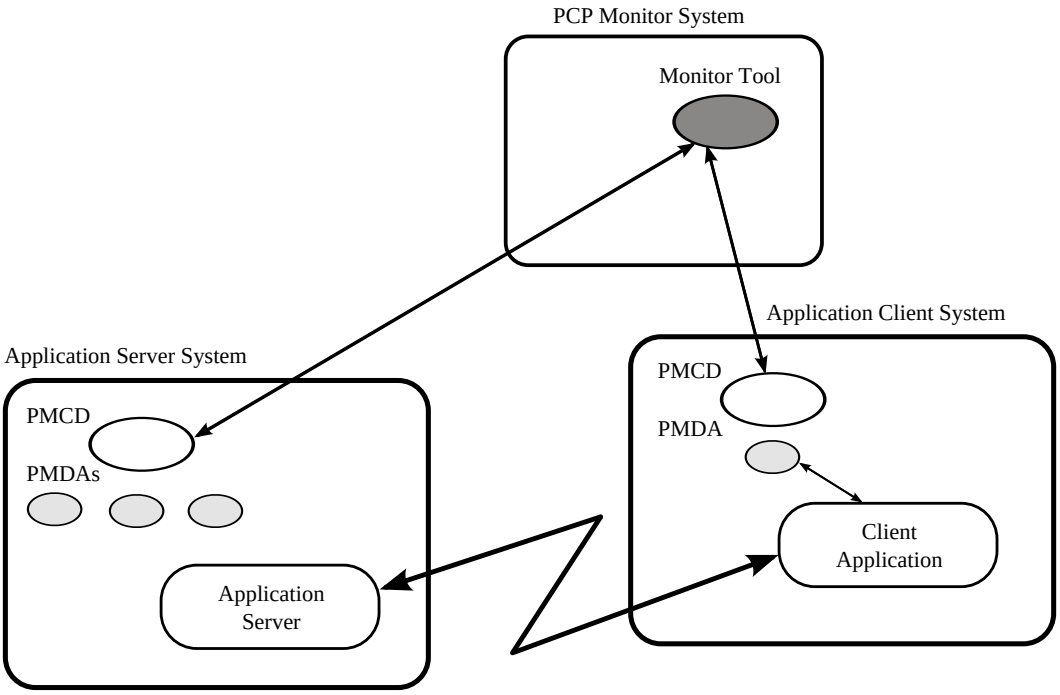
For some of these services, the PCP base product or the PCP add-on packages provide the necessary collector components. Others would require customized PMDA development, as described in the companion *Performance Co-Pilot Programmer's Guide*.

Quality of Service Measurement

Applications and services with a client-server architecture need to monitor performance at both the server side and the client side.

The arrangement in Figure 7.4, “PCP Deployment to Measure Client-Server Quality of Service” illustrates one way of measuring quality of service for client-server applications.

Figure 7.4. PCP Deployment to Measure Client-Server Quality of Service



The configuration of the PCP collector components on the Application Server System is standard. The new facility is the deployment of some PCP collector components on the Application Client System; this uses a customized PMDA and a generalization of the ICMP “ping” tool as follows:

- The `Client App` is specially developed to periodically make typical requests of the `App Server`, and to measure the response time for these requests (this is an application-specific “ping”).
- The PMDA on the Application Client System captures the response time measurements from the `Client App` and exports these into the PCP framework.

At the PCP monitor system, the performance of the system running the `App Server` and the end-user quality of service measurements from the system where the `Client App` is running can be monitored concurrently.

PCP contains a number of examples of this architecture, including the `shping` PMDA for IP-based services (including HTTP), and the `dbping` PMDA for database servers.

The source code for each of these PMDAs is readily available; users and administrators are encouraged to adapt these agents to the needs of the local application environment.

It is possible to exploit this arrangement even further, with these methods:

- Creating new instances of the `Client App` and PMDA to measure service quality for your own mission-critical services.
- Deploying the `Client App` and associated PCP collector components in a number of strategic hosts allows the quality of service over the enterprise's network to be monitored. For example, service can be monitored on the Application Server System, on the same LAN segment as the Application Server System, on the other side of a firewall system, or out in the WAN.

PCP Archive Logger Deployment

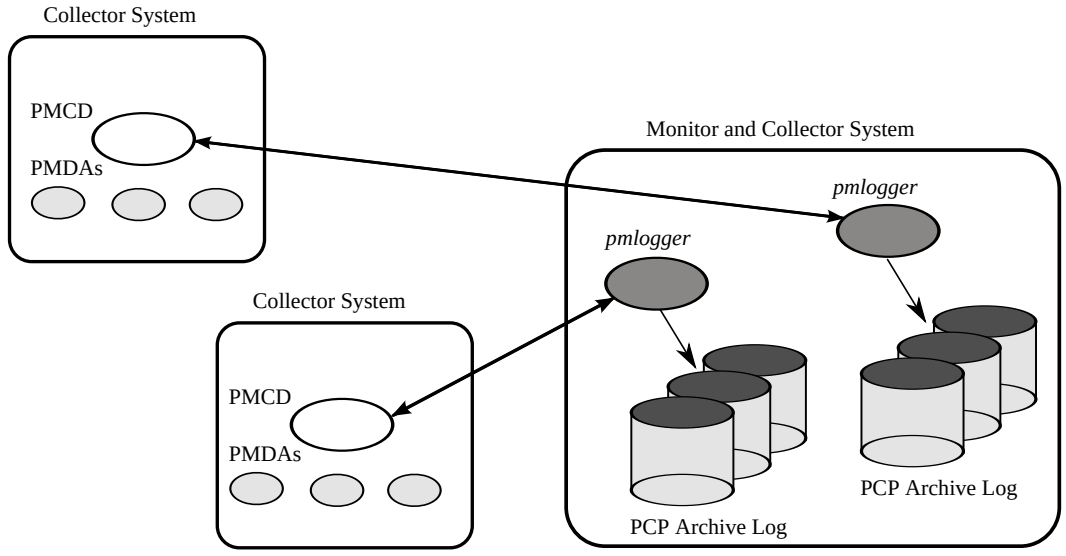
PCP archive logs are created by the **pmlogger** utility, as discussed in Chapter 6, *Archive Logging*. They provide a critical capability to perform retrospective performance analysis, for example, to detect performance regressions, for problem analysis, or to support capacity planning. The following sections discuss the options and trade-offs for **pmlogger** deployment.

Deployment Options

The issue is relatively simple and reduces to "On which host(s) should **pmlogger** be running?" The options are these:

- Run **pmlogger** on each PCP collector system to capture local performance data.
- Run **pmlogger** on some of the PCP monitor systems to capture performance data from remote PCP collector systems.
- As an extension of the previous option, designate one system to act as the PCP archive site to run all **pmlogger** instances. This arrangement is shown in Figure 7.5, "Designated PCP Archive Site".

Figure 7.5. Designated PCP Archive Site



Resource Demands for the Deployment Options

The **pmlogger** process is very lightweight in terms of computational demand; most of the (very small) CPU cost is associated with extracting performance metrics at the PCP collector system (PMCD and the PMDAs), which are independent of the host on which **pmlogger** is running.

A local **pmlogger** consumes disk bandwidth and disk space on the PCP collector system. A remote **pmlogger** consumes disk space on the site where it is running and network bandwidth between that host and the PCP collector host.

The archive logs typically grow at a rate of anywhere between a few kilobytes (KB) to tens of megabytes (MB) per day, depending on how many performance metrics are logged and the choice of sampling frequencies. There are some advantages in minimizing the number of hosts over which the disk resources for PCP archive logs must be allocated; however, the aggregate requirement is independent of where the **pmlogger** processes are running.

Operational Management

There is an initial administrative cost associated with configuring each **pmlogger** instance, and an ongoing administrative investment to monitor these configurations, perform regular housekeeping (such as rotation, compression, and culling of PCP archive log files), and execute periodic tasks to process the archives (such as nightly performance regression checking with **pmie**).

Many of these tasks are handled by the supplied **pmlogger** administrative tools and scripts, as described in the section called “Archive Log File Management”. However, the necessity and importance of these tasks favor a centralized **pmlogger** deployment, as shown in Figure 7.5, “Designated PCP Archive Site”.

Exporting PCP Archive Logs

Collecting PCP archive logs is of little value unless the logs are processed as part of the ongoing performance monitoring and management functions. This processing typically involves the use of the tools on a PCP monitor system, and hence the archive logs may need to be read on a host different from the one they were created on.

NFS mounting is obviously an option, but the PCP tools support random access and both forward and backward temporal motion within an archive log. If an archive is to be subjected to intensive and interactive processing, it may be more efficient to copy the files of the archive log to the PCP monitor system first.

Note

Each PCP archive log consists of at least three separate files (see the section called “Archive Log File Management” for details). You must have concurrent access to all of these files before a PCP tool is able to process an archive log correctly.

PCP Inference Engine Deployment

The **pmie** utility supports automated reasoning about system performance, as discussed in Chapter 5, *Performance Metrics Inference Engine*, and plays a key role in monitoring system performance for both real-time and retrospective analysis, with the performance data being retrieved respectively from a PCP collector system and a PCP archive log.

The following sections discuss the options and trade-offs for **pmie** deployment.

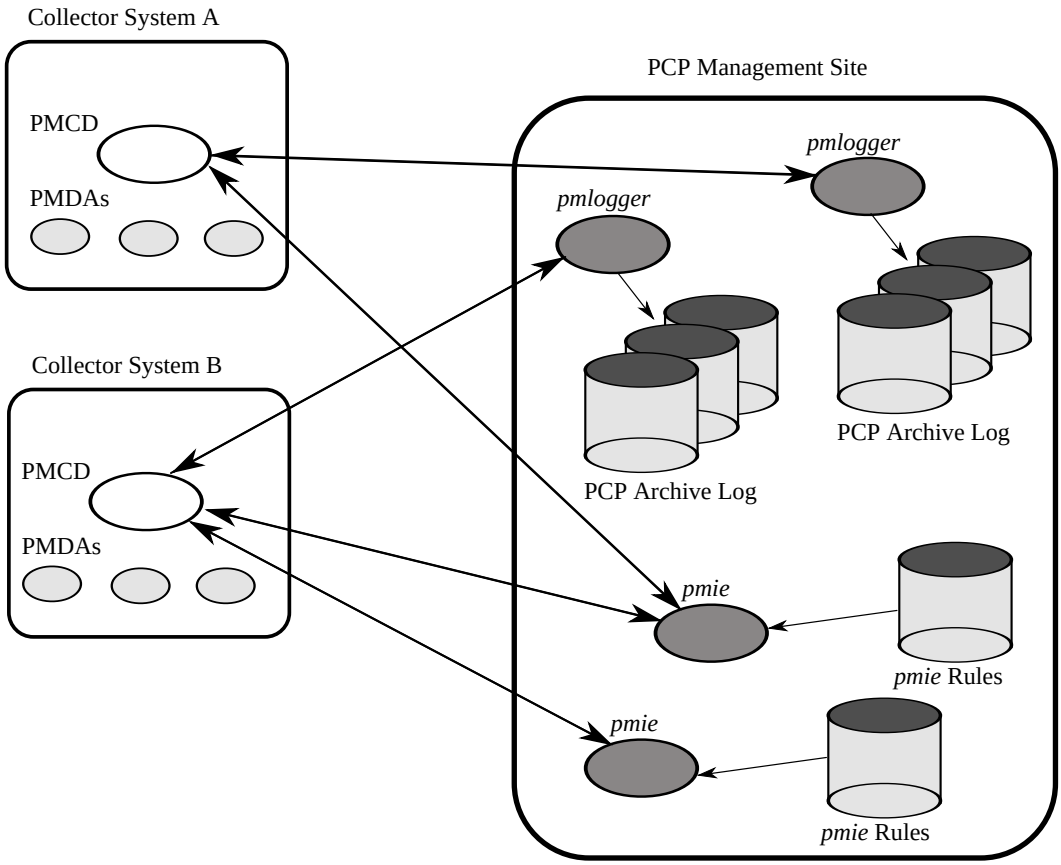
Deployment Options

The issue is relatively simple and reduces to "On which host(s) should **pmie** be running?" You must consider both real-time and retrospective uses, and the options are as follows:

- For real-time analysis, run **pmie** on each PCP collector system to monitor local system performance.
- For real-time analysis, run **pmie** on some of the PCP monitor systems to monitor the performance of remote PCP collector systems.
- For retrospective analysis, run **pmie** on the systems where the PCP archive logs reside. The problem then reduces to **pmlogger** deployment as discussed in the section called "PCP Archive Logger Deployment".
- As an example of the "distributed management with centralized control" philosophy, designate some system to act as the PCP Management Site to run all **pmlogger** and **pmie** instances. This arrangement is shown in Figure 7.6, "PCP Management Site Deployment".

One **pmie** instance is capable of monitoring multiple PCP collector systems; for example, to evaluate some universal rules that apply to all hosts. At the same time a single PCP collector system may be monitored by multiple **pmie** instances; for example, for site-specific and universal rule evaluation, or to support both tactical performance management (operations) and strategic performance management (capacity planning). Both situations are depicted in Figure 7.6, "PCP Management Site Deployment".

Figure 7.6. PCP Management Site Deployment



Resource Demands for the Deployment Options

Depending on the complexity of the rule sets, the number of hosts being monitored, and the evaluation frequency, **pmie** may consume CPU cycles significantly above the resources required to simply fetch the values of the performance metrics. If this becomes significant, then real-time deployment of **pmie** away from the PCP collector systems should be considered in order to avoid the “you're part of the problem, not the solution” scenario in terms of CPU utilization on a heavily loaded server.

Operational Management

An initial administrative cost is associated with configuring each **pmie** instance, particularly in the development of the rule sets that accurately capture and classify “good” versus “bad” performance in your environment. These rule sets almost always involve some site-specific knowledge, particularly in respect to the “normal” levels of activity and resource consumption. The **pmieconf** tool (see the section called “Creating **pmie** Rules with **pmieconf**”) may be used to help develop localized rules based upon parameterized templates covering many common performance scenarios. In complex environments, customizing these rules may occur over an extended period and require considerable performance analysis insight.

One of the functions of **pmie** provides for continual detection of adverse performance and the automatic generation of alarms (visible, audible, e-mail, pager, and so on). Uncontrolled deployment of this alarm initiating capability throughout the enterprise may cause havoc.

These considerations favor a centralized **pmie** deployment at a small number of PCP monitor sites, or in a PCP Management Site as shown in Figure 7.6, “PCP Management Site Deployment”.

However, it is most likely that knowledgeable users with specific needs may find a local deployment of **pmie** most useful to track some particular class of service difficulty or resource utilization. In these cases, the alarm propagation is unlikely to be required or is confined to the system on which **pmie** is running.

Configuration and management of a number of **pmie** instances is made much easier with the scripts and control files described in the section called “Management of **pmie** Processes”.

Chapter 8. Customizing and Extending PCP Services

Table of Contents

Performance Co-Pilot (PCP) has been developed to be fully extensible. The following sections summarize the various facilities provided to allow you to extend and customize PCP for your site:

- the section called “PMDA Customization”, describes the procedure for customizing the summary PMDA to export derived metrics formed by aggregation of base PCP metrics from one or more collector hosts.
- the section called “PCP Tool Customization”, describes the various options available for customizing and extending the basic PCP tools.
- the section called “PMNS Management”, covers the concepts and tools provided for updating the PMNS (Performance Metrics Name Space).
- the section called “PMDA Development”, details where to find further information to assist in the development of new PMDAs to extend the range of performance metrics available through the PCP infrastructure.
- the section called “PCP Tool Development”, outlines how new tools may be developed to process performance data from the PCP infrastructure.

PMDA Customization

The generic procedures for installing and activating the optional PMDAs have been described in the section called “Managing Optional PMDAs”. In some cases, these procedures prompt the user for information based upon the local system or network configuration, application deployment, or processing profile to customize the PMDA and hence the performance metrics it exports.

The summary PMDA is a special case that warrants further discussion.

Customizing the Summary PMDA

The summary PMDA exports performance metrics derived from performance metrics made available by other PMDAs. It is described completely in the **pmdasummary(1)** man page.

The summary PMDA consists of two processes:

pmie process — Periodically samples the base metrics and compute values for the derived metrics. This dedicated instance of the PCP **pmie** inference engine is launched with special command line arguments by the main process. See the section called “Introduction to **pmie**”, for a complete discussion of the **pmie** feature set.

`main` process — Reads and buffers the values computed by the **pmie** process and makes them available to the Performance Metrics Collection Daemon (PMCD).

All of the metrics exported by the summary PMDA have a singular instance and the values are instantaneous; the exported value is the correct value as of the last time the corresponding expression was evaluated by the **pmie** process.

The summary PMDA resides in the `${PCP_PMDAS_DIR}/summary` directory and may be installed with a default configuration by following the steps described in the section called “PMDA Installation on a PCP Collector Host”.

Alternatively, you may customize the summary PMDA to export your own derived performance metrics by following the steps in Procedure 8.1, “Customizing the Summary PMDA”:

Procedure 8.1. Customizing the Summary PMDA

1. Check that the symbolic constant `SYSSUMMARY` is defined in the `${PCP_VAR_DIR}/pmns/stdpmid` file. If it is not, perform the postinstall update of this file, as superuser:

   ```
   cd ${PCP_VAR_DIR}/pmns ./Make.stdpmid
   ```

2. Choose Performance Metric Name Space (PMNS) names for the new metrics. These must begin with `summary` and follow the rules described in the **pmns(5)** man page. For example, you might use `summary.fs.cache_write` and `summary.fs.cache_hit`.

3. Edit the `pmns` file in the `${PCP_PMDAS_DIR}/summary` directory to add the new metric names in the format described in the **pmns(5)** man page. You must choose a unique performance metric identifier (PMID) for each metric. In the `pmns` file, these appear as `SYSSUMMARY:0:x`. The value of *x* is arbitrary in the range 0 to 1023 and unique in this file. Refer to the section called “PMNS Management”, for a further explanation of the rules governing PMNS updates.

   For example:

   ```
   summary {
            cpu
            disk
            netif
            fs              /*new*/
   }
   summary.fs {
            cache_write     SYSSUMMARY:0:10
            cache_hit       SYSSUMMARY:0:11
   }
   ```

4. Use the local test PMNS `root` and validate that the PMNS changes are correct.

   For example, enter this command:

pminfo -n root -m summary.fs

You see output similar to the following:

```
summary.fs.cache_write PMID: 27.0.10
summary.fs.cache_hit PMID: 27.0.11
```

5. Edit the `${PCP_PMDAS_DIR}/summary/expr.pmie` file to add new **pmie** expressions. If the name to the left of the assignment operator (=) is one of the PMNS names, then the **pmie** expression to the right will be evaluated and returned by the summary PMDA. The expression must return a numeric value. Additional description of the **pmie** expression syntax may be found in the section called “Specification Language for **pmie**”.

   For example, consider this expression:

```
// filesystem buffer cache hit percentages
prefix = "kernel.all.io";          // macro, not exported
summary.fs.cache_write =
                100 - 100 * $prefix.bwrite / $prefix.lwrite;
summary.fs.cache_hit =
                100 - 100 * $prefix.bread / $prefix.lread;
```

6. Run **pmie** in debug mode to verify that the expressions are being evaluated correctly, and the values make sense.

   For example, enter this command:

   pmie -t 2sec -v expr.pmie

   You see output similar to the following:

```
summary.fs.cache_write:      ?
summary.fs.cache_hit:      ?
summary.fs.cache_write:  45.83
summary.fs.cache_hit:   83.2
summary.fs.cache_write:  39.22
summary.fs.cache_hit:  84.51
```

7. Install the new PMDA.

   From the `${PCP_PMDAS_DIR}/summary` directory, use this command:

   ./Install

   You see the following output:

```
Interval between summary expression evaluation (seconds)? [10] 10
Updating the Performance Metrics Name Space...
Installing pmchart view(s) ...
Terminate PMDA if already installed ...
Installing files ..
Updating the PMCD control file, and notifying PMCD ...
Wait 15 seconds for the agent to initialize ...
Check summary metrics have appeared ... 8 metrics and 8 values
```

8. Check the metrics.

For example, enter this command:

```
pmval -t 5sec -s 8 summary.fs.cache_write
```

You see a response similar to the following:

```
metric:    summary.fs.cache_write
host:      localhost
semantics: instantaneous value
units:     none
samples:   8
interval:  5.00 sec
63.60132158590308
62.71878646441073
62.71878646441073
58.73968492123031
58.73968492123031
65.33822758259046
65.33822758259046
72.6099706744868
```

Note that the values are being sampled here by `pmval` every 5 seconds, but **pmie** is passing only new values to the summary PMDA every 10 seconds. Both rates could be changed to suit the dynamics of your new metrics.

9. You may now create **pmchart** views, **pmie** rules, and **pmlogger** configurations to monitor and archive your new performance metrics.

PCP Tool Customization

Performance Co-Pilot (PCP) has been designed and implemented with a philosophy that embraces the notion of toolkits and encourages extensibility.

In most cases, the PCP tools provide orthogonal services, based on external configuration files. It is the creation of new and modified configuration files that enables PCP users to customize tools quickly and meet the needs of the local environment, in many cases allowing personal preferences to be established for individual users on the same PCP monitor system.

The material in this section is intended to act as a checklist of pointers to detailed documentation found elsewhere in this guide, in the man pages, and in the files that are made available as part of the PCP installation.

Archive Logging Customization

The PCP archive logger is presented in Chapter 6, *Archive Logging*, and documented in the **pmlogger(1)** man page.

The following global files and directories influence the behavior of **pmlogger**:

`${PCP_SYSCONF_DIR}/pmlogger`

Enable/disable state for the primary logger facility using this command:

```
chkconfig pmlogger on
```

`${PCP_SYSCONF_DIR}/pmlogger/config.default`	The default **pmlogger** configuration file that is used for the primary logger when this facility is enabled.
`${PCP_VAR_DIR}/config/pmlogconf/tools`	Every PCP tool with a fixed group of performance metrics contributes a **pmlogconf** configuration file that includes each of the performance metrics used in the tool, for example, `${PCP_VAR_DIR}/config/pmlogconf/pmstat` for `pmstat`.
`${PCP_PMLOGGERCONTROL_PATH}` or `${PCP_PMLOGGERCONTROL_PATH}.d` files	Defines which PCP collector hosts require **pmlogger** to be launched on the local host, where the configuration file comes from, where the archive log files should be created, and **pmlogger** startup options. These `control` files support the starting and stopping of multiple **pmlogger** instances that monitor local or remote hosts.
`/etc/cron.d/pcp-pmlogger` or `${PCP_VAR_DIR}/config/pmlogger/crontab`	Default `crontab` entries that may be merged with the `crontab` entries for the `pcp` user to schedule the periodic execution of the archive log management scripts, for example, `pmlogger_daily`.
`${PCP_LOG_DIR}/pmlogger/somehost`	The default behavior of the archive log management scripts create archive log files for the host *`somehost`* in this directory.
`${PCP_LOG_DIR}/pmlogger/somehost/Latest`	A PCP archive folio for the most recent archive for the host *`somehost`*. This folio is created and maintained by the `cron`-driven periodic archive log management scripts, for example, `pmlogger_check`. Archive folios may be processed with the `pmafm` tool.

Inference Engine Customization

The PCP inference engine is presented in Chapter 5, *Performance Metrics Inference Engine*, and documented in the **pmie(1)** man page.

The following global files and directories influence the behavior of **pmie**:

`${PCP_SYSCONF_DIR}/pmie`	Controls the pmie daemon facility. Enable using this command: `chkconfig pmie on`
`${PCP_SYSCONF_DIR}/pmie/config.default`	The **pmie** configuration file that is used for monitoring the local host when the **pmie** daemon facility is enabled in the default

	configuration. This file is created using **pmieconf** the first time the daemon facility is activated.
`${PCP_PMIECONTROL_PATH}` and `${PCP_PMIECONTROL_PATH}.d` files	Defines which PCP collector hosts require a daemon **pmie** to be monitoring from the local host, where the configuration files comes from, where the **pmie** log file should be created, and **pmie** startup options. These `control` files support the starting and stopping of multiple **pmie** instances that are each monitoring one or more hosts.
`${PCP_VAR_DIR}/config/pmieconf/*/*`	Each **pmieconf** rule definition can be found below one of these subdirectories.
`/etc/cron.d/pcp-pmie` or `${PCP_VAR_DIR}/config/pmie/crontab`	Default `crontab` entries that may be merged with the `crontab` entries for the `pcp` user to schedule the periodic execution of the **pmie_check** and **pmie_daily** scripts, for verifying that **pmie** instances are running and logs rotated.
`${PCP_LOG_DIR}/pmie/somehost`	The default behavior of the `${PCP_RC_DIR}/pmie` startup scripts create **pmie** log files for the host *somehost* in this directory.
pmie_check and **pmie_daily**	These commands are similar to the **pmlogger** support scripts, **pmlogger_check** and **pmlogger_daily**.
`${PCP_TMP_DIR}/pmie`	The statistics that **pmie** gathers are maintained in binary data structure files. These files can be found in the `${PCP_TMP_DIR}/pmie` directory.
`pmcd.pmie` metrics	The PMCD PMDA exports information about executing **pmie** processes and their progress in terms of rule evaluations and action execution rates. If **pmie** is running on a system with a PCP collector deployment, the **pmcd** PMDA exports these metrics via the `pmcd.pmie` group of metrics.

PMNS Management

This section describes the syntax, semantics, and processing framework for the external specification of a Performance Metrics Name Space (PMNS) as it might be loaded by the PMAPI routine **pmLoadNameSpace**; see the **pmLoadNameSpace(3)** man page. This is usually done only by **pmcd**, except in rare circumstances such as the section called “Customizing the Summary PMDA”.

The PMNS specification is a simple text source file that can be edited easily. For reasons of efficiency, a binary format is also supported; the utility `pmnscomp` translates the ASCII source format into binary format; see the **pmnscomp(1)** man page.

PMNS Processing Framework

The PMNS specification is initially passed through **pmcpp(1)**. This means the following facilities may be used in the specification:

- C-style comments
- `#include` directives
- `#define` directives and macro substitution
- Conditional processing with `#ifdef`, `#ifndef`, `#endif`, and `#undef`

When **pmcpp(1)** is executed, the standard include directories are the current directory and `${PCP_VAR_DIR}/pmns`, where some standard macros and default specifications may be found.

PMNS Syntax

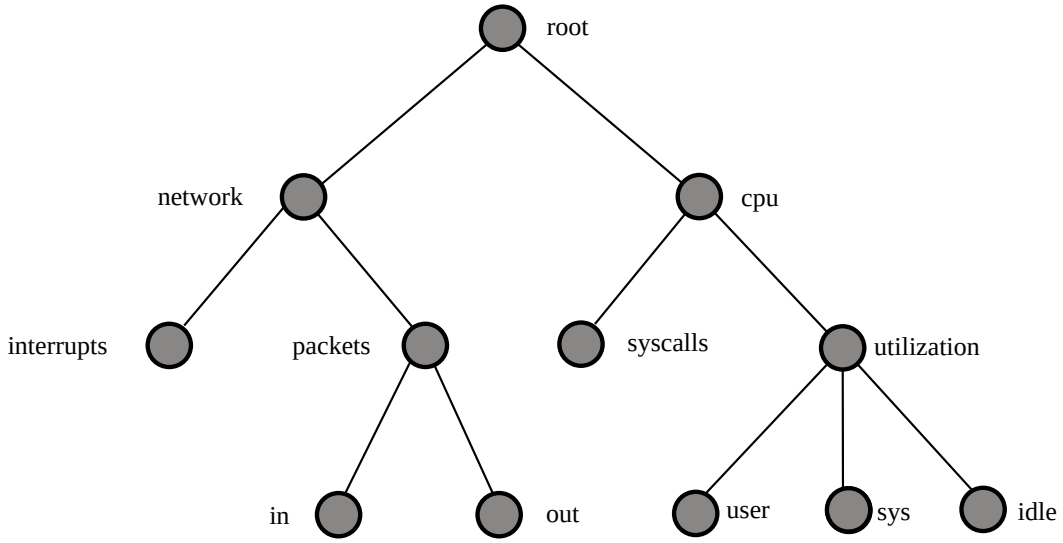
Every PMNS is tree structured. The paths to the leaf nodes are the performance metric names. The general syntax for a non-leaf node in PMNS is as follows:

```
pathname {
        name    [pmid]
        ...
}
```

Here `pathname` is the full pathname from the root of the PMNS to this non-leaf node, with each component in the path separated by a period. The root node for the PMNS has the special name `root`, but the prefix string `root.` must be omitted from all other `pathnames`.

For example, refer to the PMNS shown in Figure 8.1, “Small Performance Metrics Name Space (PMNS)”. The correct pathname for the rightmost non-leaf node is `cpu.utilization`, not `root.cpu.utilization`.

Figure 8.1. Small Performance Metrics Name Space (PMNS)



Each component in the pathname must begin with an alphabetic character and be followed by zero or more alphanumeric characters or the underscore (_) character. For alphabetic characters in a component, uppercase and lowercase are significant.

Non-leaf nodes in the PMNS may be defined in any order desired. The descendent nodes are defined by the set of `names`, relative to the pathname of their parent non-leaf node. For descendent nodes, leaf nodes have a `pmid` specification, but non-leaf nodes do not.

The syntax for the `pmid` specification was chosen to help manage the allocation of Performance Metric IDs (PMIDs) across disjoint and autonomous domains of administration and implementation. Each `pmid` consists of three integers separated by colons, for example, `14:27:11`. This is intended to mirror the implementation hierarchy of performance metrics. The first integer identifies the domain in which the performance metric lies. Within a domain, related metrics are often grouped into clusters. The second integer identifies the cluster, and the third integer, the metric within the cluster.

The PMNS specification for Figure 8.1, “Small Performance Metrics Name Space (PMNS)” is shown in Example 8.1, “PMNS Specification”:

Example 8.1. PMNS Specification

```
/*
* PMNS Specification
*/
#define KERNEL 1
root {
       network
       cpu
}
#define NETWORK 26
network {
       interrupts    KERNEL:NETWORK:1
       packets
}
network.packets {
```

```
        in      KERNEL:NETWORK:35
        out     KERNEL:NETWORK:36
}
#define CPU 10
cpu {
        syscalls    KERNEL:CPU:10
        utilization
}
#define USER 20
#define SYSTEM 21
#define IDLE 22
cpu.utilization {
        user    KERNEL:CPU:USER
        sys     KERNEL:CPU:SYSTEM
        idle    KERNEL:CPU:IDLE
}
```

For complete documentation of the PMNS and associated utilities, see the **pmns(5)**, **pmnsadd(1)**, **pmnsdel(1)** and **pmnsmerge(1)** man pages.

PMDA Development

Performance Co-Pilot (PCP) is designed to be extensible at the collector site.

Application developers are encouraged to create new PMDAs to export performance metrics from the applications and service layers that are particularly relevant to a specific site, application suite, or processing environment.

These PMDAs use the routines of the `libpcp_pmda` library, which is discussed in detail in the *Performance Co-Pilot Programmer's Guide*.

PCP Tool Development

Performance Co-Pilot (PCP) is designed to be extensible at the monitor site.

Application developers are encouraged to create new PCP client applications to monitor or display performance metrics in a manner that is particularly relevant to a specific site, application suite, or processing environment.

Client applications use the routines of the PMAPI (performance metrics application programming interface) described in the *Performance Co-Pilot Programmer's Guide*. At the time of writing, native PMAPI interfaces are available for the C, C++ and Python languages.

Appendix A. Acronyms

Table A.1, “Performance Co-Pilot Acronyms and Their Meanings ” provides a list of the acronyms used in the Performance Co-Pilot (PCP) documentation, help cards, man pages, and user interface.

Table A.1. Performance Co-Pilot Acronyms and Their Meanings

Acronym	Meaning
API	Application Programming Interface
DBMS	Database Management System
DNS	Domain Name Service
DSO	Dynamic Shared Object
I/O	Input/Output
IPC	Interprocess Communication
PCP	Performance Co-Pilot
PDU	Protocol data unit
PMAPI	Performance Metrics Application Programming Interface
PMCD	Performance Metrics Collection Daemon
PMD	Performance Metrics Domain
PMDA	Performance Metrics Domain Agent
PMID	Performance Metric Identifier
PMNS	Performance Metrics Name Space
TCP/IP	Transmission Control Protocol/Internet Protocol
